AMERICAN PSYCHIATRIC ASSOCIATION

One of a series from
"The Many Faces of

STELAZINE®
brand of
trifluoperazine HCl
in Psychiatry"

Shaman Mask,
Tlingit Culture, Alaska.
Represents man who turned
into a land otter.

From the collection of
The University Museum
University of Pennsylvania
Philadelphia, Pa.
Reproduced with permission.

REMOVE THE MASK OF SCHIZOPHRENIC SYMPTOMS

'STELAZINE' PROVIDES EFFECTIVE CONTROL OF HALLUCINATIONS, DELUSIONS, ANXIETY AND OTHER SCHIZOPHRENIC SYMPTOMS.
BECAUSE IT APPEARS TO HAVE AN ACTIVATING EFFECT, 'STELAZINE' IS ESPECIALLY USEFUL IN WITHDRAWN, APATHETIC OR DETACHED PATIENTS.

- EFFECTIVELY CONTROLS PSYCHOTIC SYMPTOMS
- SELDOM CAUSES EXCESSIVE SEDATION
- CONVENIENT B.I.D. DOSAGE

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications
Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F*) or other phenothiazines:* Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg., and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only) 10 mg./ml.

brand of **STELAZINE®** Tablets: 5 and 10 mg.
TRIFLUOPERAZINE HCL

HELPS WITHDRAWN PATIENTS BECOME MORE RESPONSIVE

a valuable link to the resources of the American Psychiatric Association

for institutions and agencies concerned with the care of the mentally disabled

Enrollment in the Hospital & Community Psychiatry Service brings multiple copies of *Hospital & Community Psychiatry* into member agencies every month, keeping staff up to date on developments and issues in the mental health field, offering new ideas and fresh perspectives, and serving as a useful resource in staff development and training programs.

Hospital & Community Psychiatry is just one of the benefits of membership in the H&CP Service. Others include a film library containing more than a hundred films specially chosen for their usefulness in staff development and community education programs; supplementary mailings of important books, reports, articles, or other material of special interest to administrators or clinicians; reduced registration fees at the annual fall Institute on Hospital & Community Psychiatry; and, on request, information and consultation from the professional staff of the American Psychiatric Association. The H&CP Service also sponsors the annual Achievement Awards competition, which gives special recognition to outstanding programs for the mentally ill and mentally retarded.

Please send me information about membership in the Hospital & Community Psychiatry Service.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Wash., D.C. 20009; there will usually be a charge for granting this permission.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal's* Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

Informed consent. Manuscripts that report the results of experimental investigation on human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure had been fully explained.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHORS' CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

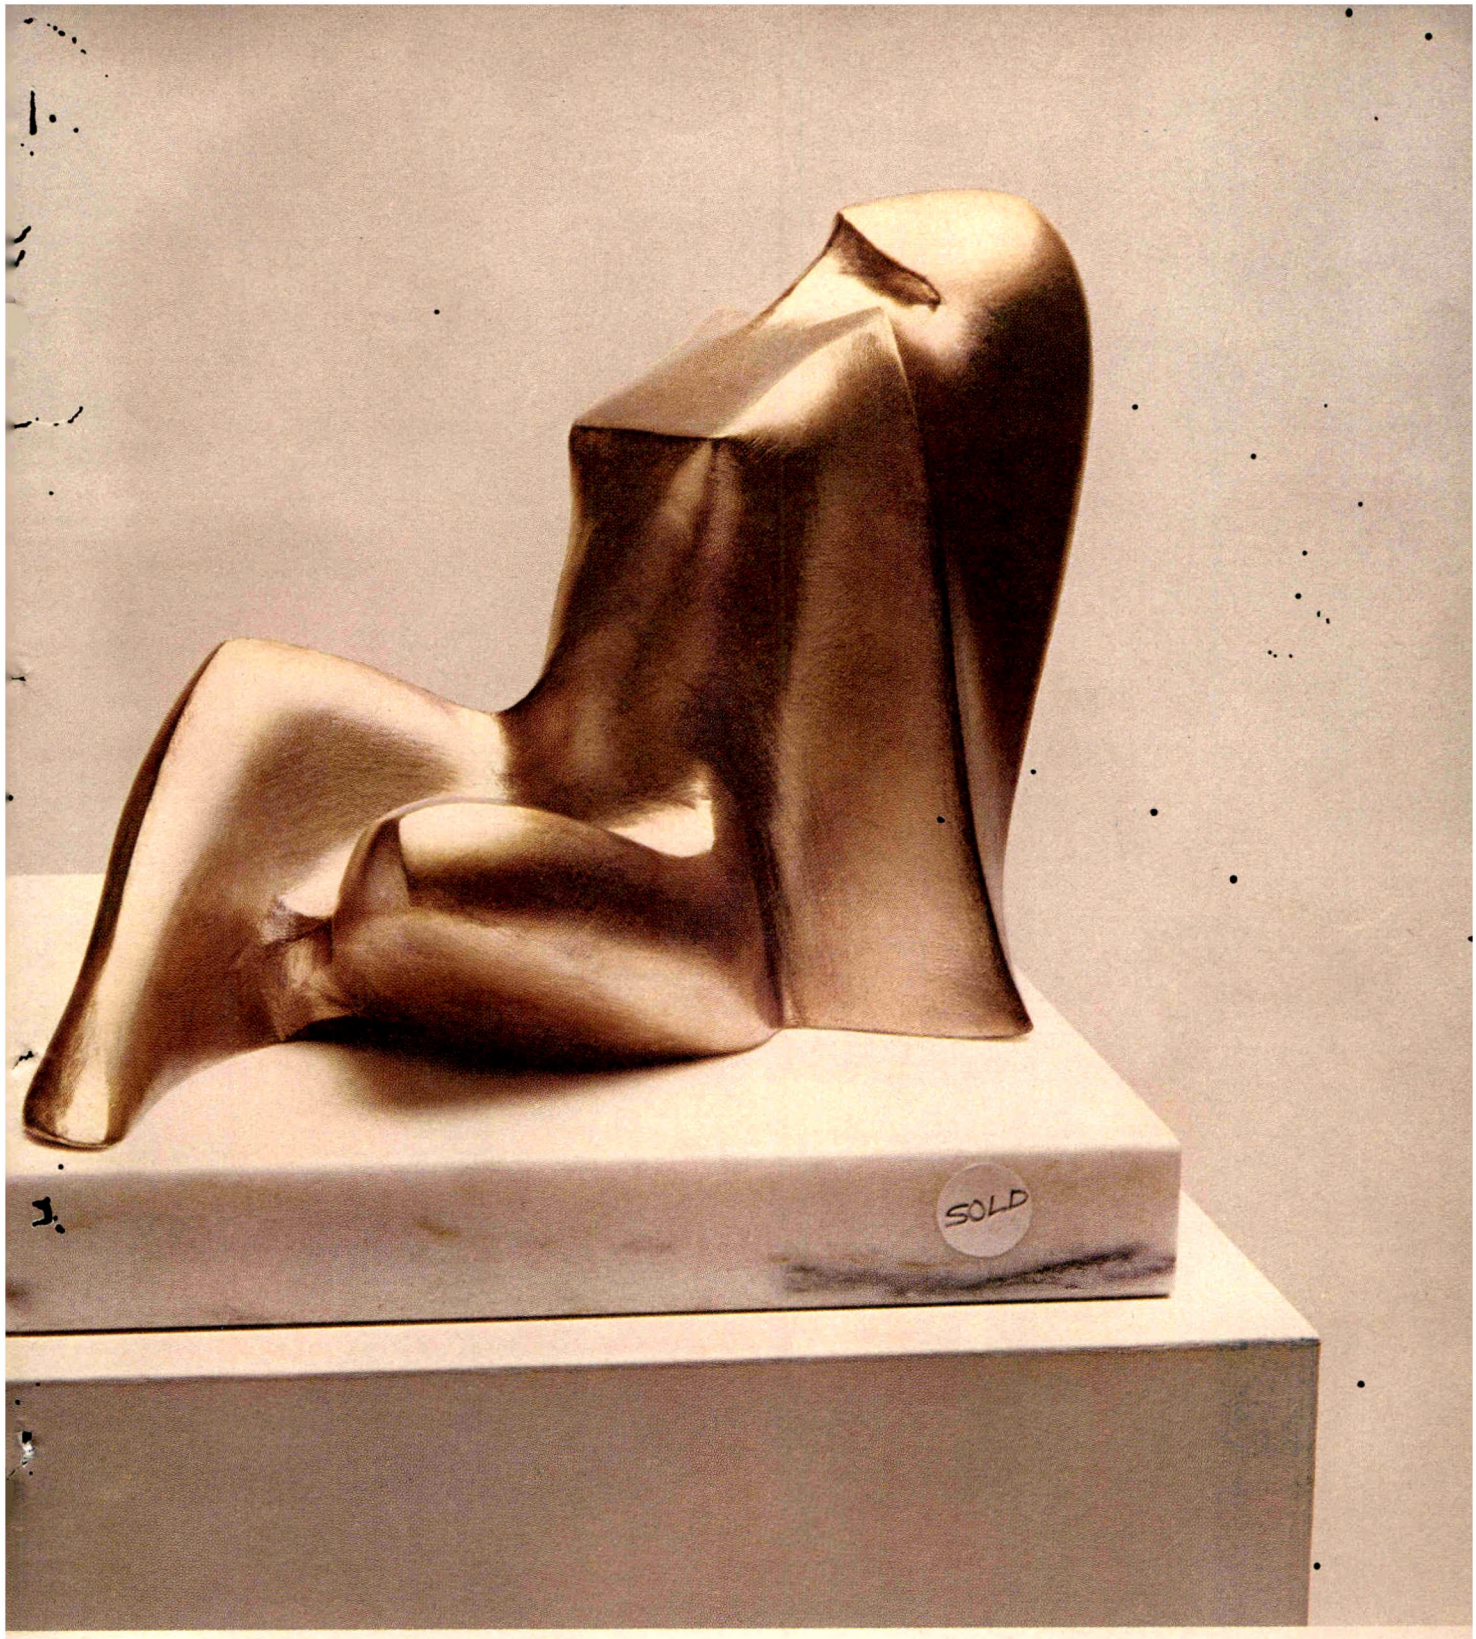
Released from symptoms of psychotic depression...

Productive again.



By helping to reduce the frequency and intensity of psychotic symptoms, Navane (thiothixene) often permits resumption of more normal, more productive living.

The antipsychotic effectiveness of Navane—with relatively little drowsiness—helps patients remain more active, more alert, better able to meet the ordinary demands of life.

Cardiovascular side effects such as hypotension and nonspecific EKG changes are relatively rare with Navane (thiothixene). Extrapyramidal symptoms have been reported, but are usually controlled by reduction in dosage and/or administration of antiparkinson drugs.

Once you've controlled acute psychosis or psychotic depression, some patients can be maintained on a simple once-a-day dose. This once-a-day regimen can reduce the risk of missed doses with no loss of efficacy.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

Navane®

(thiothixene) (thiothixene hydrochloride)

Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg/Concentrate 5 mg/ml

Once-a-day–to help control symptoms of psychosis

For prescribing information, including adverse reactions and contraindications please see following page of this advertisement.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg (thiothixene hydrochloride) Concentrate: 5 mg/ml, Intramuscular: 2 mg/ml

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration – As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate—In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor elevating action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg. of thiothixene in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

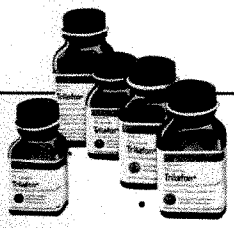
Help restore reality.

Trilafon®
brand of
perphenazine, NF
for management of disturbed behavior in schizophrenic and manic states

- low dose, high potency phenothiazine useful for inpatient and outpatient treatment
- helps orient psychiatric patients to their surroundings
- effective with minimal sedation, usually produces little lethargy or drowsiness

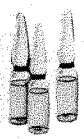


Versatile Dosage	
Injection	5 mg/ml, 1 ml ampul
Concentrate	16 mg/5 ml, 120 ml bottle
Tablets	2,4,8,16 mg
REPETABS® Tablets 8 mg brand of repeat-action tablets	

Please see next page for prescribing information.

Trilafon®
brand of perphenazine, NF

For management of schizophrenic and manic disorders in psychiatric hospitals, mental health clinics, and with outpatient treatment



TABLETS
for maintenance or control of patients in hospital or home

BENEFITS
- generally improve cooperation and communication
- decrease need for custodial care, hasten discharge

CONCENTRATE
for maintenance or control of uncooperative in-hospital patients

- easily mixes with most liquids
- ensures easy, steady, certain administration

INJECTION
for emergency control of uncooperative in-hospital patients

- usually takes effect in 10 minutes
- average duration of effect is 6 hours

TRILAFON® Tablets
brand of perphenazine, NF

REPETABS® Tablets
Concentrate
Injection

CONTRAINDICATIONS TRILAFON is contraindicated in drug-associated central nervous system depression (barbiturates, alcohol, narcotics, analgesics, antihistamines). Perphenazine is contraindicated in the presence of existing blood dyscrasias, bone marrow depression and pre-existing liver damage, and in patients who are hypersensitive to perphenazine.

TRILAFON **Injection** should not be given to patients in coma or severely depressed states.

WARNINGS **Dosage in pregnancy:** Perphenazine should only be given to pregnant patients when, in the judgment of the physician, the potential benefits outweigh the possible risks.

Perphenazine can lower the convulsive threshold in susceptible individuals; it should be used with caution in patients with convulsive disorders. If the patient is being treated with an anticonvulsant agent, increased dosage of that agent may be required when perphenazine is used concomitantly.

Perphenazine should be used with caution in patients with psychic depression.

Perphenazine is not recommended for children under 12 years of age.

Perphenazine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or operating machinery.

PRECAUTIONS As with any potent medication, patients receiving perphenazine should be under medical supervision, particularly if they are receiving high doses. Patients who have had any severe reaction to phenothiazines or to imipramine should be treated cautiously, under close medical supervision.

Although the following adverse reactions have not been reported in patients treated with perphenazine, the possibility that they might occur with TRILAFON should be considered: blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, eosinophilia); liver damage (biliary stasis); narrowing of the visual fields; pigmentation of the retina, cornea, or lens; cerebral edema; polyphagia; photophobia; hyperpyrexia.

If hypotension develops, levarterenol (norepinephrine) can be used, but not epinephrine, because epinephrine's action is blocked and partly reversed by perphenazine. Severe, acute hypotension has occurred with the use of phenothiazines and is of particular concern in patients with mitral insufficiency or pheochromocytoma.

A significant rise in body temperature may indicate an idiosyncratic reaction to perphenazine; treatment with perphenazine should be stopped if this occurs.

The antiemetic effect of perphenazine can obscure signs of toxicity due to overdosage of other drugs, or mask the symptoms of disease (eg, brain tumor or intestinal obstruction).

Contact dermatitis has been reported with a perphenazine solution; therefore, contact of hands or clothing by those handling perphenazine solutions should be avoided.

POTENTIATION Since phenothiazines can potentiate the central-nervous-system-depressant actions of opiates, antihistamines, barbiturates, and alcohol, less than the usual dosage of these agents is required when they are administered concomitantly with TRILAFON. Patients should be cautioned that their response to alcohol may be increased while they are being treated with TRILAFON.

Phenothiazines also potentiate the effects of atropine, heat, and phosphorus insecticides, and should be used with caution in persons exposed to these agents.

ADVERSE REACTIONS *Extrapyramidal reactions:* dystonia including protrusion, discoloration, aching and rounding of the tongue; tonic spasm of the masticatory muscles, tight feeling in the throat, slurred speech, dysphagia, oculogyric crisis, trismus, torticollis, retrocollis, muscle weakness, and aching and numbness of the limbs; akathisia; motor restlessness; dyskinesia, parkinsonism; hyperreflexia; and ataxia. The incidence and severity of these reactions usually increase with increased dosage, but have occurred in some patients receiving low dosage. Reduction in dosage or treatment with an antispasmodic agent will usually control extrapyramidal reactions. In some instances, however, these reactions may persist after discontinuation of treatment with perphenazine.

Persistent tardive dyskinesia: As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities. There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine, vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Allergic reactions: erythema, pruritus, urticaria, eczema, anaphylactoid reactions, and local and generalized edema. In extremely rare instances, individual idiosyncrasy or hypersensitivity to phenothiazines has resulted in cerebral edema, circulatory collapse, and death. Photosensitization, asthma, and exfoliative dermatitis have also occurred in patients treated with phenothiazines.

Autonomic reactions: blurred vision, dry mouth or salivation, nasal congestion, nausea, vomiting, hypertension, tachycardia, hypotension, anorexia, urinary frequency or incontinence, and constipation. Significant autonomic effects have been infrequent in patients receiving less than 24 mg. perphenazine daily.

Other reactions: endocrine disturbances (lactation, gynecomastia, galactorrhea, disturbances in the menstrual cycle), headaches, mild insomnia, altered cerebrospinal fluid proteins, ECG abnormalities, reactivation of psychosis, paradoxical excitement, paranoid-like reactions, catatonia, and systemic lupus erythematosus-like syndrome. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active. The following adverse reactions, though rare, have also been reported to be associated with perphenazine treatment: agranulocytosis; jaundice; hyperpigmentation of the skin; grand mal convulsions; failure of ejaculation; hyperglycemia.

Side effects with intramuscular TRILAFON **Injection** have been infrequent and transient. Dizziness or significant hypotension after treatment with TRILAFON (perphenazine) **Injection** is a rare occurrence.

Three Treatment Centers

Three treatment centers provide individually prescribed programs of care, education, treatment and training for children, adolescents and adults with learning disabilities, neurological impairment, mental retardation or emotional disturbance.

Advantage: the availability of a **large, trained and experienced staff,** exchanging ideas and insights in a comprehensive program of supportive environment and individualized treatment.

Advantage: **geographically separated** to provide the proper residential milieu . . . yet near enough to benefit from the combined training and experience of a wide range of staff members.

The Oaks — A residential psychiatric treatment center for emotionally disturbed children and adolescents between the ages of six and 18. Coeducational, Austin. In addition, the Center provides a Short Term Adolescent Center and a six bed intensive care unit.

The San Marcos Treatment Center — a facility with three campuses designed for individuals with psychiatric, neurological, and intellectual difficulties who have evidenced a need for a 24-hour therapeutic milieu.

The Center offers a broad spectrum of services to both mentally retarded individuals and those with psychiatric disorders. In addition to a structured therapeutic environment, individual and group psychotherapy services are available to each resident. Clinical supervision and support services are provided by the Center psychiatrists.

The Ranch Treatment Center — located in the suburbs of Austin the Center provides both long-term and intermediate tenure services to multi-handicapped male adolescents and adults whose primary diagnostic classifications are in areas of mental retardation and mental illness. All residents receive program services which may permit their early discharge to the less restrictive settings of community-based programs.

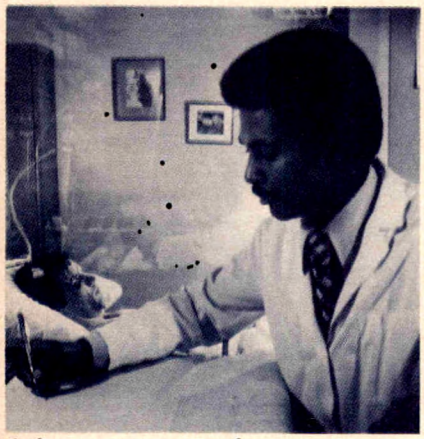
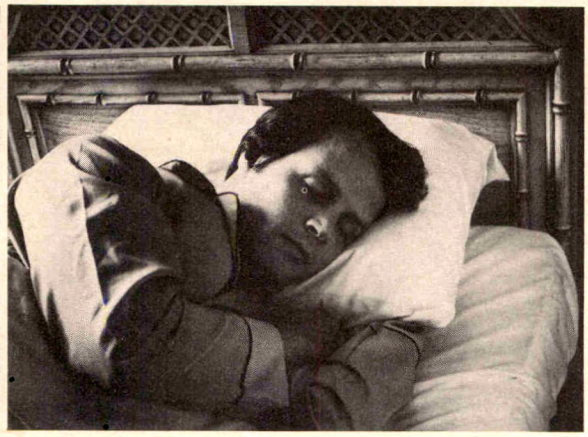
The August 1976 issue of



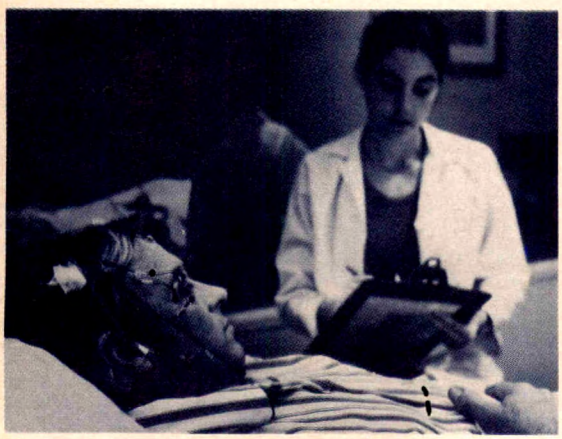
The American Journal of Psychiatry



will feature

- **Overview: Psychiatric Sequelae to Multiple Trauma by Nathan Schnaper and R. Adams Cowley**

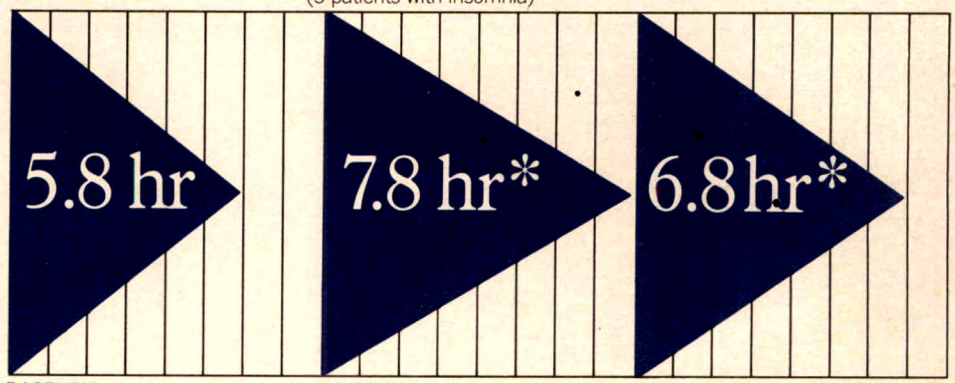
From the sleep research laboratory:



Dalmane® (flurazepam HCl) proved the most effective hypnotic over 14 nights...[1]

14 consecutive nights:
3 in sleep laboratory, 8 at home,
3 in sleep laboratory

...and now, the only one proved effective over 28 nights.[2,3]



28 consecutive nights:
3 in sleep laboratory, 7 at home,
4 in sleep laboratory, 10 at home,
4 in sleep laboratory[3]

For those patients who need it, Dalmane (flurazepam HCl) alone provides continued effectiveness[2,3]

Since insomnia is often transient and intermittent, the prolonged administration of a hypnotic is generally not necessary or recommended. But for those patients whose insomnia is a chronic problem, the continued effectiveness of Dalmane is a decided benefit. Even at the end of a 28-night medication period, patients with chronic insomnia were falling asleep faster, spending less time awake during the night, and sleeping substantially longer on Dalmane 30 mg *h.s.* than on baseline placebo nights (average results). This effectiveness was proved[2] and confirmed[3] in two independent sleep research studies using a new 47-night protocol. When similarly evaluated, pentobarbital was ineffective at the end of two weeks.[2]

TOTAL SLEEP TIME (MEAN)[3]
(5 patients with insomnia)

*Significantly increased over baseline placebo ($P<.05$).

In previous studies[1], chloral hydrate and glutethimide lost most or all effectiveness

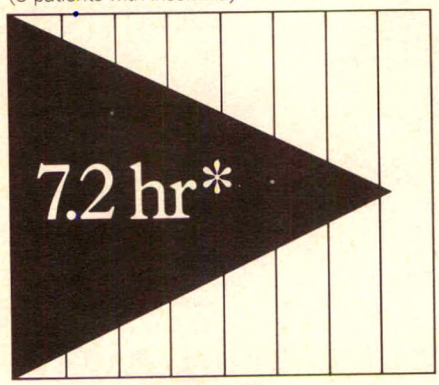
In fact, continued effectiveness for both inducing and maintaining sleep over 14 consecutive nights[1] has long been an exclusive benefit of Dalmane. No other available sleep agent, including chloral hydrate or glutethimide,[1] has been able to demonstrate such effectiveness in the sleep research laboratory.

The safety record of Dalmane (flurazepam HCl) is well established

Dalmane is relatively safe and well tolerated. Prolonged administration is not generally necessary, but if used repeatedly, periodic blood counts and liver and kidney function tests should be performed.

Dalmane®
(flurazepam HCl)
relatively safe... no need to increase dosage.

ROCHE



Please see following page for a summary of complete product information.

1,5,7,14,28 nights... as needed, the effectiveness of **Dalmane**® one *h.s.* (flurazepam HCl) C IV meets the challenge of insomnia

One 30-mg capsule *h.s.*—usual adult dosage (15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.

- **Patients fall asleep rapidly, sleep longer on a single *h.s.* dose.**
- **Nighttime awakenings and time spent awake are reduced**
- **Effectiveness maintained without dosage increase from night to night**
- **Patients generally awaken refreshed; morning "hangover" is infrequent**

TOTAL SLEEP TIME (OVERALL MEAN)[3]
(5 patients with insomnia)

DALMANE (flurazepam HCl)
NIGHTS 1-3, 12-14, 26-28

Before prescribing Dalmane (flurazepam HCl), please consult complete product information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia of poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

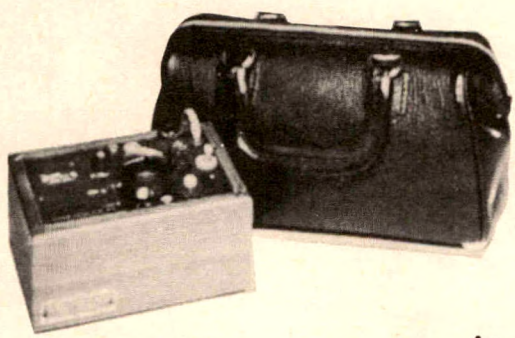
MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC.**



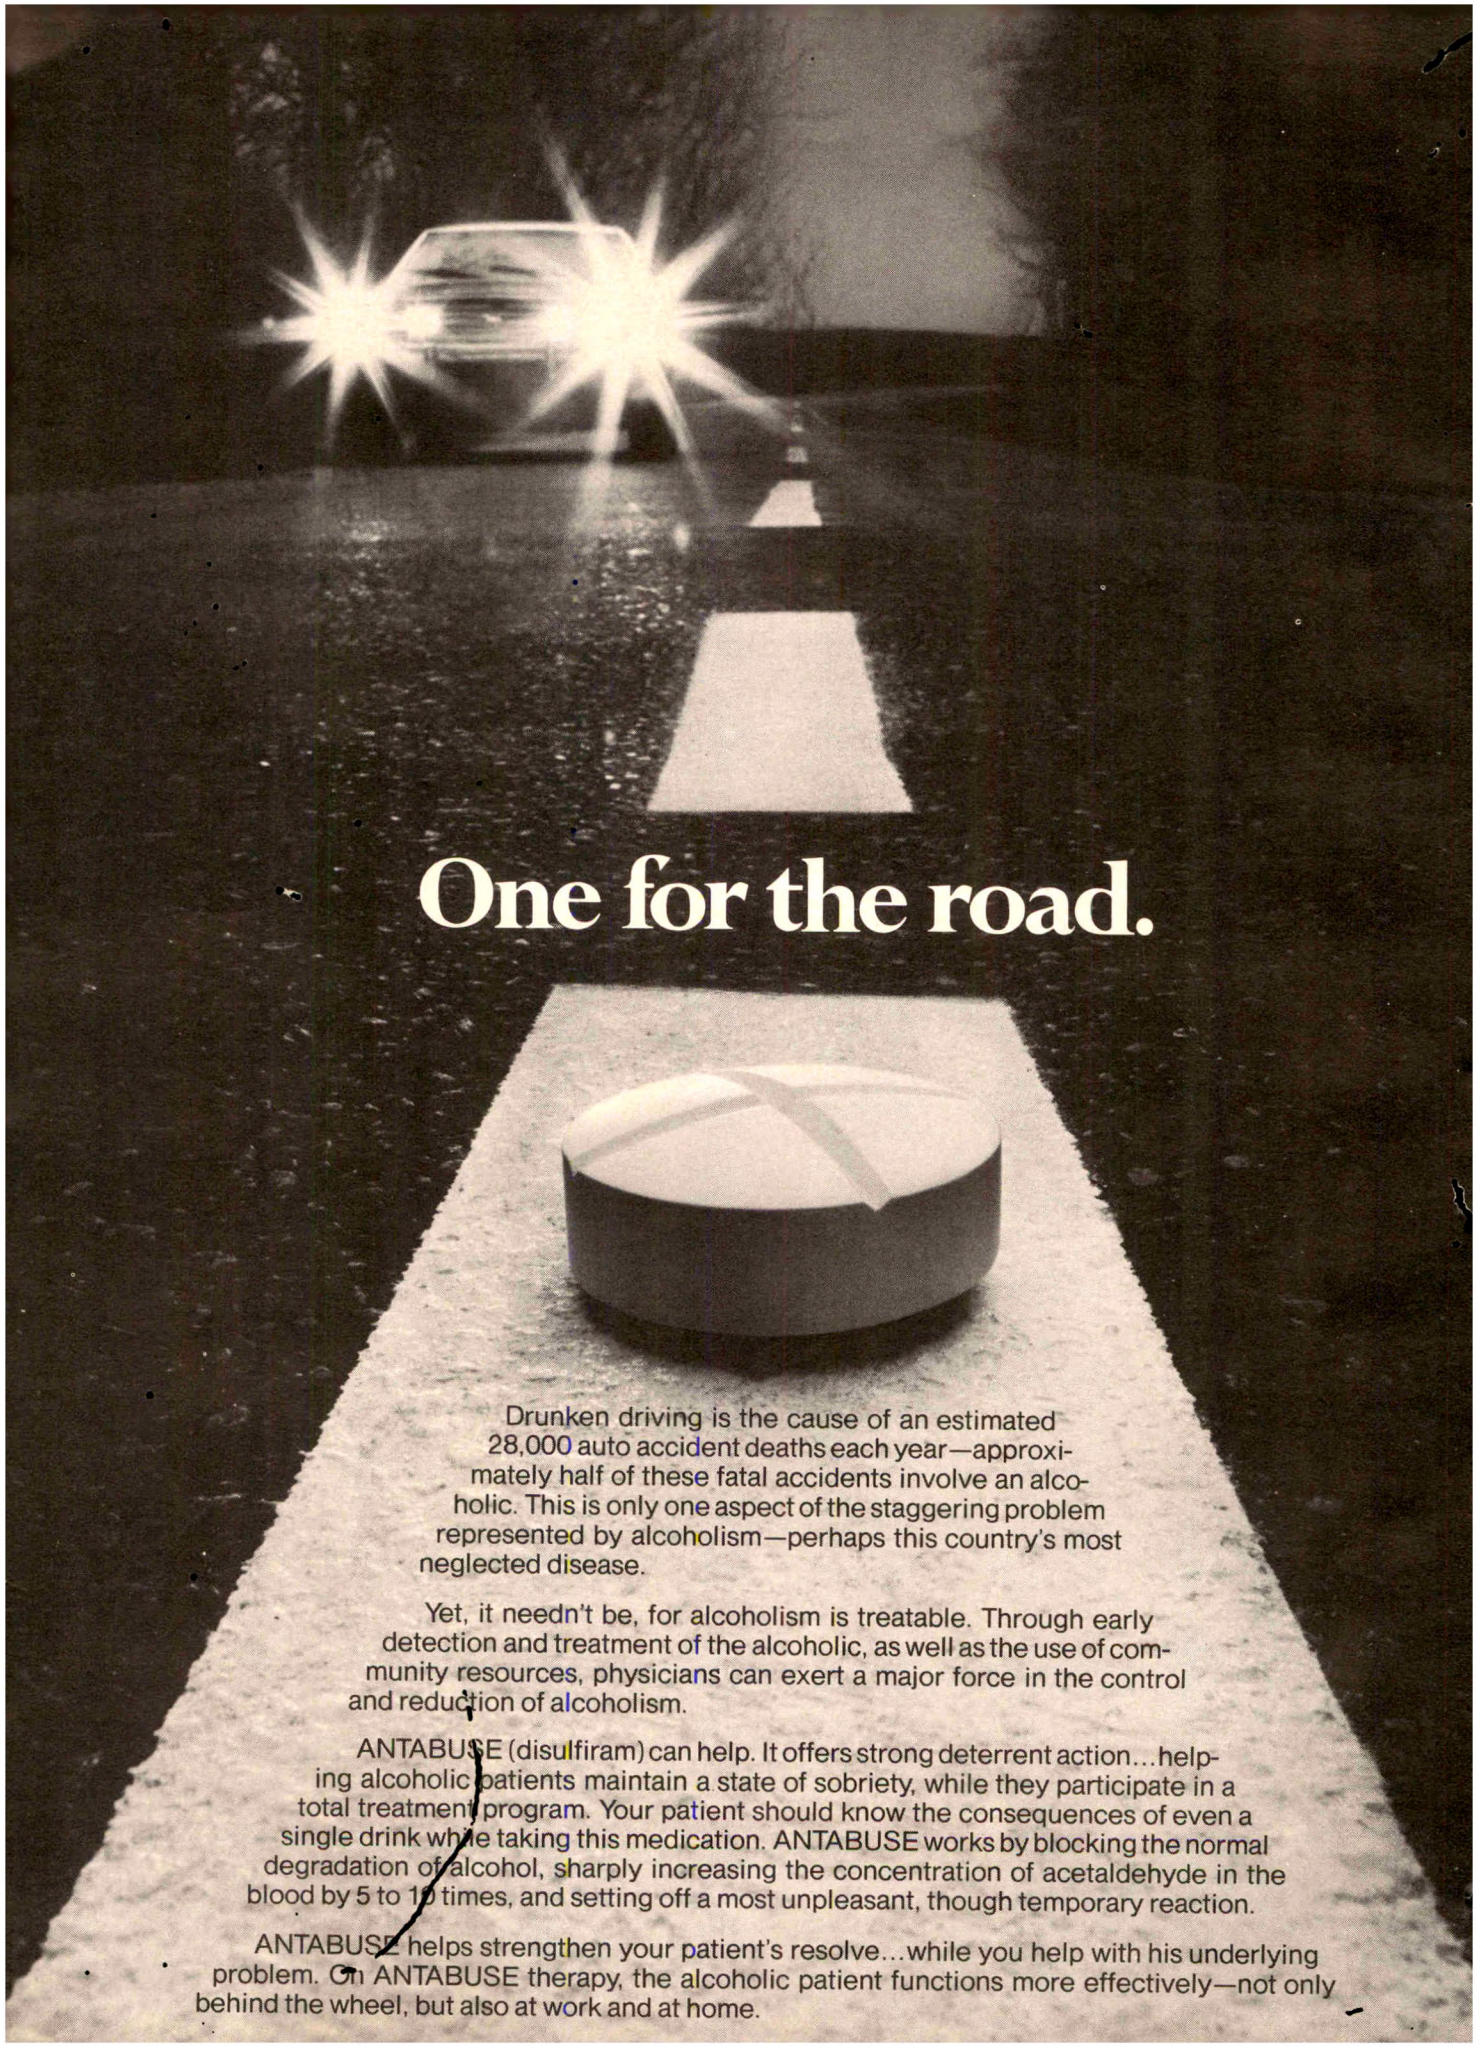
The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.



The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

For more detailed information, and bibliography of over 200 references, write to:

REUBEN REITER, Sc.D., INC. 187 Sylvan Ave., Leonia, N.J. 07605 — Tel. (201) 944-1211

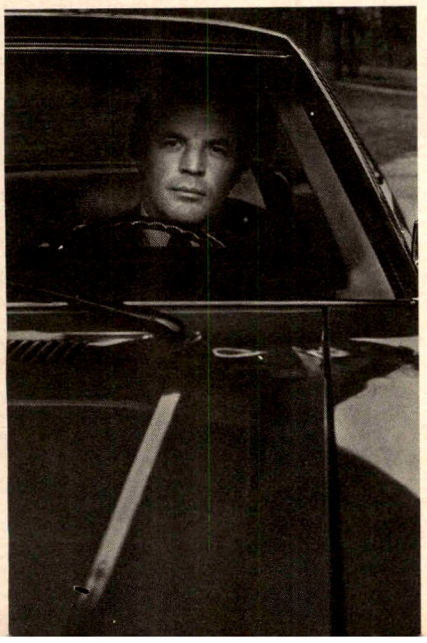
Drunken driving is the cause of an estimated 28,000 auto accident deaths each year—approximately half of these fatal accidents involve an alcoholic. This is only one aspect of the staggering problem represented by alcoholism—perhaps this country's most neglected disease.

Yet, it needn't be, for alcoholism is treatable. Through early detection and treatment of the alcoholic, as well as the use of community resources, physicians can exert a major force in the control and reduction of alcoholism.

ANTABUSE (disulfiram) can help. It offers strong deterrent action...helping alcoholic patients maintain a state of sobriety, while they participate in a total treatment program. Your patient should know the consequences of even a single drink while taking this medication. ANTABUSE works by blocking the normal degradation of alcohol, sharply increasing the concentration of acetaldehyde in the blood by 5 to 10 times, and setting off a most unpleasant, though temporary reaction.

ANTABUSE helps strengthen your patient's resolve...while you help with his underlying problem. On ANTABUSE therapy, the alcoholic patient functions more effectively—not only behind the wheel, but also at work and at home.

BRIEF SUMMARY
(For full prescribing information, see package circular.)
ANTABUSE® (disulfiram) In Alcoholism
INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)
CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, *e.g.* cough syrups, tonics, and the like, should not be given ANTABUSE.
ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.



WARNINGS: ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.
The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.
THE ANTABUSE-ALCOHOL REACTION:
ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.
The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.
The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.
DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.
Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.
It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.
Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.
CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.
USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.
PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)
Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.
Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.
ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)
Optic neuritis, peripheral neuritis, and polyneuritis may occur following administration of ANTABUSE.
Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.
In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.
Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.
One case of cholestatic hepatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.
DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.
INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.
MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.
NOTE: Occasional patients, while seemingly on adequate maintenance dose of ANTABUSE, report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.
DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years.
TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, such a test reaction should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.
However, where a test reaction is deemed necessary, the suggested procedure is as follows:
After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (1/2 oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops, no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.
MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokalemia has been reported.
HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100.
No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000. **7626**

New York, N.Y. 10017

in clinically significant depression...

penetrating the symptom barrier to productive psychotherapy

symptoms often interfere with therapy

In clinically significant depression, the patient often becomes barricaded behind his own symptoms during psychotherapy. Because these symptoms can be so sharply defined and somatic in expression, he may reject the fact that they are psychic in origin. Sleep disturbance, gastrointestinal complaints, anorexia, chronic fatigue, and other psychosomatic symptoms may so preoccupy—or overwhelm—the depressed patient that truly productive therapeutic sessions are difficult to achieve. Instead of being able to concentrate on the core emotional problems of the depression itself, he may for example go on at length about how broken his sleep is or keep reiterating (while the therapeutic hour slips by) how physically miserable he feels.

ELAVIL®
(AMITRIPTYLINE HCl, MSD)
to help penetrate the symptom barrier in depression requiring medication

ELAVIL, a highly effective tricyclic antidepressant, will often alleviate these symptoms. With the help of ELAVIL, sleep disturbance—so common in clinically depressed patients and often the symptom that distresses them most—as

well as other "barrier symptoms" may be lessened to the point where they no longer come between you and the patient.

psychotherapy takes direction

As these preoccupying complaints are lifted, psychotherapy sessions can become more productive. Patients are enabled to respond more fruitfully during therapeutic hours and to resume or pursue more efficiently the necessary activities in their personal lives.

meeting therapeutic goals

And as the antidepressant activity of ELAVIL (Amitriptyline HCl, MSD) takes hold, it helps relieve the depressive condition itself. Sometimes only a minimum of actual psychotherapy is required. The patient may experience a more rapid recovery—while you conserve valuable time.

Prescribe ELAVIL then, to help lighten the patient's burden in depression—and yours in its management.

ELAVIL should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Its safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

TABLETS: 10 mg, 25 mg, 50 mg, 75 mg, and 100 mg
INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

an antidepressant with an anxiety-reducing sedative component to its action

UNIVERSITY OF MEDICINE & DENTISTRY LIBRARY

MSD

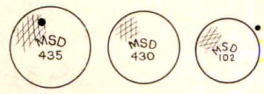
For a brief summary of prescribing information, please see following page.

MSD
MERCK SHARP & DOHME

addendum

ELAVIL®



(AMITRIPTYLINE HCl | MSD)

Five tablet strengths for differing patient needs. The variety of dosage strengths available with ELAVIL makes possible great prescribing flexibility.

Once-a-day dosage at bedtime is an appropriate way to start—and maintain—many patients on therapy. The simplicity of this regimen helps improve patient compliance. ELAVIL may also be prescribed in divided daily doses.

A sedative effect may be apparent before the antidepressant effect of ELAVIL is noted. An adequate therapeutic effect may take as long as 30 days to develop.

100 mg
75 mg
50 mg

These tablets may be advantageous when initiating therapy with once-daily bedtime dosage in adult outpatients. The usual starting dosage is 75 mg daily. Therapy may be initiated with 50 to 100 mg daily. This may be increased by 25 or 50 mg as necessary in the bedtime dose to a total of 150 mg per day.

These tablets may also be convenient for many hospitalized patients. These patients may need 100 mg a day initially which can be increased gradually to 200 mg a day if necessary. A small number of such patients may need as much as 300 mg a day.

25 mg 

This tablet may prove useful when initiating therapy with divided daily doses in adult outpatients. Starting dosage is usually 75 mg daily. If necessary, this dosage may be increased gradually to a total of 150 mg a day. Increases are made preferably in the late afternoon or bedtime doses.

10 mg 

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher doses.

NOTE: The usual maintenance dosage of ELAVIL is 50 to 100 mg per day which may be given in a single dose preferably at bedtime. In some patients 40 mg per day is sufficient. This drug is not recommended for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required; paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported. Use with caution in patients with impaired liver function.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue, rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; tablets containing 75 mg and 100 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

NEW ORAL CONCENTRATE

Loxitane® C

LOXAPINE HYDROCHLORIDE

Lederle

25 mg base/ml* In bottles of 4 fl. oz.

Effectiveness – the only clue that it's there

DESCRIPTION

*Each ml contains the equivalent of 25 mg loxapine base as the HCl.

LOXITANE *loxapine*, a dibenzoxazepine compound represents a new subclass of tricyclic antipsychotic agent, chemically distinct from the thioxanthenes, butyrophenones, and phenothiazines. Chemically, it is 2-chloro-11-(4-methyl-1-piperazinyl)dibenz[b,f][1,4]oxazepine. It is present in the oral concentrate primarily as the HCl.

ACTIONS

Pharmacologically, loxapine is a tranquilizer for which the exact mode of action has not been established. However, changes in the level of excitability of subcortical inhibitory areas have been observed in several animal species in association with such manifestations of tranquilization as calming effects and suppression of aggressive behavior.

In normal human volunteers, signs of sedation were seen within 20 to 30 minutes after administration, were most pronounced within 1 1/2 to 3 hours, and lasted through 12 hours. Similar timing of primary pharmacologic effects was seen in animals.

Absorption of loxapine following oral or parenteral administration is virtually complete. The drug is removed rapidly from the plasma and distributed in tissues. Animal studies suggest an initial preferential distribution in lungs, brain, spleen, heart, and kidney. Loxapine is metabolized extensively and is excreted mainly in the first 24 hours. Metabolites are excreted in the urine in the form of conjugates and in the feces unconjugated.

INDICATIONS

LOXITANE C *loxapine hydrochloride* is indicated for the manifestations of schizophrenia.

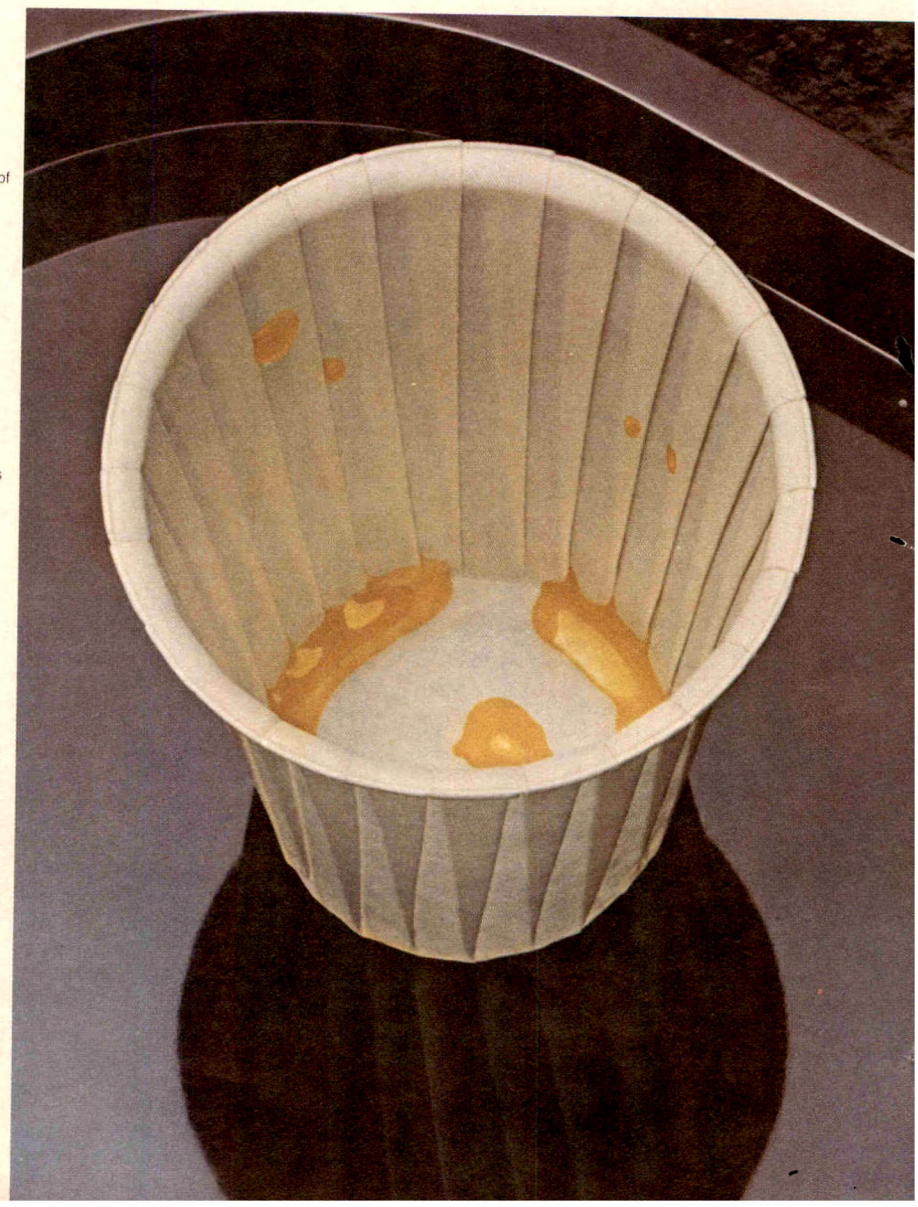
LOXITANE has not been shown effective in the management of behavioral complications in patients with mental retardation.

CONTRAINDICATIONS

LOXITANE is contraindicated in comatose or severe drug-induced depressed states (alcohol, barbiturates, narcotics, etc.)

LOXITANE is contraindicated in individuals with known hypersensitivity to the drug.

WARNINGS



Usage in Pregnancy: Safe use of LOXITANE C *loxapine hydrochloride* during pregnancy or lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the benefits of treatment be weighed against the possible risks to mother and child. No embryotoxicity or teratology was observed in studies in rats, rabbits or dogs, although with the exception of one rabbit study, the highest dosage was only two times the maximum recommended human dose and in some studies they were below this dose. Perinatal studies have shown renal papillary abnormalities in offspring of rats treated from mid-pregnancy with doses of 0.6 and 1.8 mg/kg, doses which approximate the usual human dose but which are considerably below the maximum recommended human dose.

Usage in Children: Studies have not been performed in children; therefore this drug is not recommended for use in children below the age of 16.

LOXITANE C *loxapine hydrochloride*, like other tranquilizers, may impair mental and/or physical abilities, especially during the first few days of therapy. Therefore, ambulatory patients should be warned about activities requiring alertness (e.g, operating vehicles or machinery), and about concomitant use of alcohol and other CNS depressants.

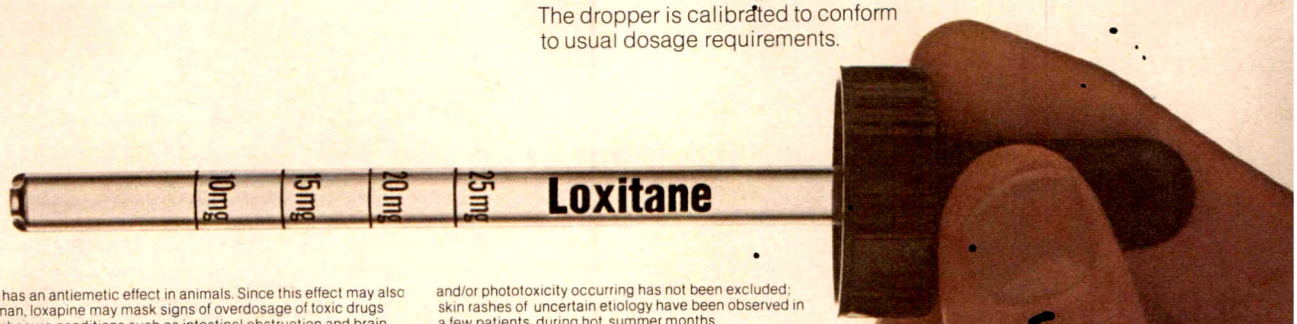
PRECAUTIONS

LOXITANE should be used with extreme caution in patients with a history of convulsive disorders since it lowers the convulsive threshold. Seizures have been reported in epileptic patients receiving LOXITANE at antipsychotic dose levels, and may occur even with maintenance of routine anticonvulsant drug therapy.

Tasteless in orange, grapefruit and pineapple juices

Highly acceptable to patients who prefer medication in fruit juices, and a logical alternative to tablets or capsules when good patient management depends on uninterrupted treatment. LOXITANE C Oral Concentrate is as easy to take as the fruit juice in which it may be administered.

Same efficacy as LOXITANE Capsules



Efficacy that speaks for itself with substantial reduction in the symptoms of schizophrenia.

Same favorable side effects profile as with LOXITANE Capsules[1]

In 31 studies involving 469 schizophrenic patients, certain favorable trends were exhibited in the LOXITANE side effects profile; these require further tests and broader clinical experience for confirmation.[1]

Same daily dosage schedule as with LOXITANE Capsules

The dropper is calibrated to conform to usual dosage requirements.

Loxapine has an antiemetic effect in animals. Since this effect may also occur in man, loxapine may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

LOXITANE should be used with caution in patients with cardiovascular disease. Increased pulse rates have been reported in the majority of patients receiving antipsychotic doses; transient hypotension has been reported. In the presence of severe hypotension requiring vasopressor therapy, the preferred drugs may be norepinephrine or angiotensin. Usual doses of epinephrine may be ineffective because of inhibition of its vasopressor effect by loxapine.

The possibility of ocular toxicity from loxapine cannot be excluded at this time. Therefore, careful observation should be made for pigmentary retinopathy and lenticular pigmentation since these have been observed in some patients receiving certain other antipsychotic drugs for prolonged periods.

Because of possible anticholinergic action, the drug should be used cautiously in patients with glaucoma or a tendency to urinary retention, particularly with concomitant administration of anticholinergic-type antiparkinson medication.

ADVERSE REACTIONS

CNS Effects: Manifestations of adverse effects on the central nervous system, other than extrapyramidal effects, have been seen infrequently. Drowsiness, usually mild, may occur at the beginning of therapy or when dosage is increased.

It usually subsides with continued LOXITANE therapy. The incidence of sedation has been less than that of certain aliphatic phenothiazines and slightly more than the piperazine phenothiazines. Dizziness, faintness, staggering gait, muscle twitching, weakness, and confusional states have been reported.

Extrapyramidal Reactions—Neuromuscular (extrapyramidal) reactions during the administration of LOXITANE C *loxapine hydrochloride* have been reported frequently, often during the first few days of treatment. In most patients, these reactions involved Parkinson-like symptoms such as tremor, rigidity, excessive salivation, and masked facies. Akathisia (motor restlessness) also has been reported relatively frequently. These symptoms are usually not severe and can be controlled by reduction of LOXITANE dosage or by administration of antiparkinson drugs in usual dosage. Dystonic and dyskinetic reactions have occurred less frequently, but may be more severe. Dystonias include spasms of muscles of the neck and face, tongue protrusion, and oculogyric movement. Dyskinetic reaction has been described in the form of choreo-athetoid movements. These reactions sometimes require reduction or temporary withdrawal of LOXITANE dosage in addition to appropriate counteractive drugs.

Persistent Tardive Dyskinesia—As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy,especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movement of the tongue, face, mouth, or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinson agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Cardiovascular Effects: Tachycardia, hypotension, hypertension, lightheadedness, and syncope have been reported.

A few cases of ECG changes similar to those seen with phenothiazines have been reported. It is not known whether these were related to loxapine administration.

Skin: Dermatitis, edema (puffiness of face), pruritus, and seborrhea have been reported with loxapine. The possibility of photosensivitity and/or phototoxicity occurring has not been excluded; skin rashes of uncertain etiology have been observed in a few patients during hot summer months.

Endocrine Effects: No endocrine abnormalities have been reported.

Anticholinergic Effects: Dry mouth, nasal congestion, constipation, and blurred vision have occurred; these are more likely to occur with concomitant use of antiparkinson agents.

Other Adverse Reactions: Nausea, vomiting, weight gain, weight loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, and polydipsia have been reported in some patients.

DOSAGE AND ADMINISTRATION

LOXITANE C *loxapine hydrochloride* is administered orally usually in divided doses two to four times a day. Daily dosage (in terms of base equivalents) should be adjusted to the individual patient's needs as assessed by the severity of symptoms and previous history of response to antipsychotic drugs. Initial dosage of 10 mg twice daily is recommended, although in severely disturbed patients initial dosage up to a total of 50 mg daily may be desirable. Dosage should then be increased fairly rapidly over the first seven to ten days until there is effective control of psychotic symptoms. The usual therapeutic and maintenance range is 60 mg to 100 mg daily. However, as with other antipsychotic drugs, some patients respond to lower dosage and others require higher dosage for optimal benefit. Daily dosage higher than 250 mg is not recommended. For maintenance therapy, dosage should be reduced to the lowest level compatible with symptom control; many patients have been maintained satisfactorily at dosages in the range of 20 mg to 60 mg daily.

LOXITANE C Oral Concentrate should be mixed with orange or grapefruit juice shortly before administration.

Use only the enclosed calibrated (10 mg, 15 mg, 20 mg, 25 mg) dropper for dosage.

HOW SUPPLIED

LOXITANE C *loxapine hydrochloride* is supplied in bottles of 4 fl. oz. (120 ml) with calibrated dropper. Each ml contains the equivalent of 25 mg loxapine base as the HCl. Rev 4/76

4th edition

A Psychiatric Glossary

Edited by a subcommittee of the AMERICAN PSYCHIATRIC ASSOCIATION Committee on Public Information.

The new Fourth Edition marks a striking expansion of definitions: 400 terms have been added and many of the terms appearing in earlier editions have received revised explanations. In addition to the GLOSSARY's continuing value to lawyers, teachers, journalists, social workers, and others, the new edition will be useful to medical students and first year residents in psychiatry.

Some major changes in the Fourth Edition:

- Expansion from 102 to 156 pages to accommodate 400 new terms
- New tables of terms in seven areas of contemporary concern
  - Drugs Used in Psychiatry
  - Legal Terms
  - Neurologic Deficits
  - Psychological Tests
  - Research Terms
  - Schools of Psychiatry
  - Sleep Disorders
- A comprehensive set of terms used in behavior therapy is included for the first time.

Paperback edition—$3.00 each, (See coupon for bulk discounts), may be ordered from the AMERICAN PSYCHIATRIC ASSOCIATION, Publications Sales, 1700 18th St. N.W., Washington, D.C. 20009.

Hardback edition—$7.95 may be ordered from Basic Books, Inc., 10 East 53rd Street, New York, New York 10022.

LIBRIUM®
(chlordiazepoxide HCl)
5 mg, 10 mg, 25 mg capsules

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

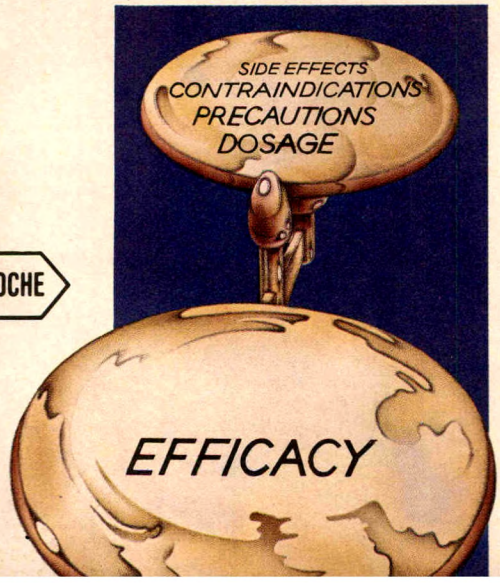
Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

ROCHE

Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

SAFETY. IT'S A QUESTION OF BALANCE.

In choosing a tranquilizer for the patient whose excessive anxiety is disrupting psychotherapy there are a number of things to consider. One is effectiveness. A second is safety.



The first is more easily established. The second may be ascertained by comparison. In other words, with safety there is the question of balancing a drug's potential benefits against any potential risks.

When the antianxiety agent you are considering is Librium, you should know that it has a wide margin of safety.

The most common side effects of Librium are dose-related and thus largely avoidable. There appears to be a low incidence of drug dependence and tolerance. Librium rarely has any adverse effects on the cardiovascular or respiratory systems, and there are relatively few cases of known toxicity attributable to Librium.

You already know that Librium is effective. But you should also know that Librium, used in proper dosage, rarely interferes with mental acuity and thus is unlikely to interfere with the psychotherapeutic process. In addition, Librium is used concomitantly with many primary medications.

Librium. All in all, a very good balance.

Haldol®
(haloperidol)
tablets/concentrate/injection

For prompt control with minimal risk of hypotension or oversedation

Highly effective in a wide range of psychotic symptoms[1-7]
such as hallucinations, delusions, suspiciousness, hostility, mania, psychomotor agitation, etc., in both acute and chronic disorders.

Helps keep patients functioning and avoid hospitalization.[1-3]
HALDOL haloperidol usually leaves most patients alert and responsive, able to function at work and at home without impairment, and more amenable to other therapeutic measures.

Permits aggressive titration to effective dosage levels[1,4]
up to 100 mg/day orally (with minimal risk of usual troublesome reactions) to achieve optimal response when patient is inadequately controlled at lower dosage...to help you rapidly control and stabilize new patients, promptly regain control during periods of exacerbation.

Common side effects easily controlled.[1,2,4]
Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Reduces risk of certain troublesome reactions.[1,2,4-6]
Transient hypotension occurs rarely and severe orthostatic hypotension has not been reported. Marked sedation is rare, although some instances of drowsiness have been reported. In addition, with chronic use, it is unlikely to cause hepatic damage, serious hematologic reactions, photosensitivity reactions and skin rashes...and has minimal effect on renal function.

Please turn page for information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions.

Important: Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

Haldol® (haloperidol)

tablets/concentrate/injection

For prompt control of psychotic symptoms with minimal risk of hypotension or oversedation

A Dosage Form for Every Need:

5 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg., 5 mg. and 10 mg.

A tasteless, odorless, colorless liquid concentrate for better patient acceptability: 2 mg. per ml.

A rapid-acting injection for psychiatric emergencies: 5 mg. per ml., with 1.8 mg. methylparaben and 0.2 mg. propylparaben per ml., and lactic acid for pH adjustment to 3.4±0.2.

Indications: HALDOL haloperidol is indicated for use in the management of manifestations of psychotic disorders.

It is also indicated for the control of tics and vocal utterances of Gilles de la Tourette's syndrome.

Contraindications: HALDOL haloperidol is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy:*** Safe use of HALDOL haloperidol in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of haloperidol orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children: Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL haloperidol, decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL haloperidol may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL haloperidol should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL haloperidol may lower the convulsive threshold. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant antiparkinson medication is required, it may have to be continued after HALDOL haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson agents, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of antiparkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Persistent Tardive Dyskinesia*—Tardive dyskinesia may appear during long-term therapy or after therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. There is no known effective treatment. All antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL haloperidol is administered or prescribed. 9/74

I [illegible] DEPRESSIVE NEUROSIS...

For Brief Summary, please see following page.

SANDOZ

75-379

RESULTS OFTEN SEEN IN A WEEK

Because the somatic and psychic complaints that accompany depressive neurosis can interfere with the treatment of the underlying psychopathology—rapid relief of these symptoms is often crucial to therapy.

In 14 double-blind studies of four weeks duration, 339 patients with depressive neurosis received Mellaril. In these studies, 55% of the overall improvement was observed by the end of the first week, and a total of 293 patients (86%) improved during the four weeks.*

Mellaril usually does not cause euphoria or undue sedation and is nonaddicting. Patients, therefore, generally remain alert and better able to respond to therapy. (The physician should, however, caution patients against participating in activities which require complete mental alertness, e.g., driving.)

*Data on file at Sandoz Pharmaceuticals.

MELLARIL®
(THIORIDAZINE)

TABLETS: 25 mg and 50 mg thioridazine HCl, U.S.P.

for the short-term treatment of moderate to marked depression with variable degrees of anxiety in patients with depressive neurosis

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling. The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

Dosage: Dosage must be individualized according to the degree of mental and emotional disturbance, and the smallest effective dosage should be determined for each patient. In adults with depressive neurosis the usual starting dosage is 25 mg t.i.d. and the dosage ranges from 10 mg b.i.d. to q.i.d. in milder cases to 50 mg t.i.d. or q.i.d. for more severely disturbed patients; the total daily dose ranges from 20 mg to a maximum of 200 mg.

JUDD MARMOR, M.D.

Presidential Address: Psychiatry 1976—The Continuing Revolution

BY JUDD MARMOR, M.D.

As WE MEET here in this 200th year since our founding fathers declared their independence from colonial rule, we take pride in the fact that one of the signers of that historic Declaration was Benjamin Rush, the physician whom we honor as the father of American psychiatry. A perceptive statement that he made after the War of Independence had been won, namely, that although the war was over, the revolution was not and that the struggle to achieve its ultimate goals had to continue, has provided the theme for our meeting this year. In our context, "The Continuing Revolution" implies that despite the progress we have made, the struggle to control and eliminate mental illness is a continuing one. In the remarks that follow I shall try to explore some of the ramifications of this theme in four major areas: 1) the internal affairs of our Association, 2) our external relationships, 3) the theory and practice of our discipline, and finally, 4) some aspects of the contemporary American social scene.

INTERNAL AFFAIRS

With regard to internal affairs, we continue to grow in both size and complexity. When I joined the APA in 1939 our membership was in the neighborhood of 2,200. Today it is more than 10 times that number and represents 90% of all of the psychiatrists in the United States. We have expanded our ranks to include psychiatric residents as Members-in-Training, and they are playing an increasingly important role in our organization. In the past year we have also extended membership to first-year psychiatric residents, who for the first time will now be able to enter our Association as Provisional Members.

Thirty years ago the entire budget of the American Psychiatric Association was $60,000 a year. Our 1976 budget is well over 5 million dollars, reflecting not only the increase in the size of our membership but also the enormous expansion of the activities of our Association in our efforts to deal with the growing number of scientific, educational, and clinical issues confronting us. Like other organizations we have been beset by the extraordinary inflationary pressures of the past several years, and we have tried assiduously to eliminate overlapping, duplication, and wastefulness wherever possible. We have been greatly assisted in these efforts by our new Deputy Director for Business Administration, Jack White, who has made a tremendous contribution toward putting the Association's affairs under sound fiscal management.

We place no premium on expansion as a value in and of itself, but the increased demands on our Association in a variety of areas have mandated an inevitable growth. New staff personnel are being added in the areas of education and peer review, and our Department of Government Relations has been expanded to enable us to respond more effectively to state and national legislative proposals in the area of mental health. To facilitate these latter efforts the Board of Trustees and the Assembly of District Branches have established a Joint Commission on Government Relations, consisting of a chairman and seven Area Council members, each of whom is in communication with a network of representatives in the district branches. Despite its necessarily limited budget, this joint commission is operating with increasing efficiency and has improved our efforts to keep abreast of legislative issues affecting the mental health field at the local and state as well as the national level.

Upon the strong recommendation of the Assembly of District Branches, a new Council on Children, Adolescents, and the Family has been created; it will give

Presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

Dr. Marmor was 104th President of the American Psychiatric Association, 1975–1976. He is Franz Alexander Professor of Psychiatry, University of Southern California School of Medicine, Los Angeles, Calif. 90033.

needed emphasis to an important sector of our discipline that is so relevant to the preventive aspects of psychiatry.

Our district branches now number 70, with our latest addition being that of Puerto Rico. As we meet here just across the water from this newest district branch, I extend to these colleagues our warmest welcome. We are looking forward with pleasure to the excellent postconvention meeting in San Juan that they have helped to arrange.

The most important internal activities in our Association during the past year have been the efforts to broaden its democratic base in accord with the historic conference that took place in Key Biscayne more than a year ago. The impetus for this conference stemmed from a strong wish to increase the degree of grassroots participation in the affairs and decisions of our Association. Two major mandates issued from the conference: to democratize the structure of the Assembly of District Branches so that members could be more involved in choosing their geographical representatives and influencing their policies, and in line with this change, to then transfer much of the decision-making power of the Association from the Board of Trustees to the Assembly of District Branches. Toward these goals, a joint ad hoc committee of the Board and the Assembly, together with members of the Constitution and By-Laws Committee, held a series of meetings over the past year during which they laboriously evolved a new constitution that will begin to fulfill the Key Conference mandates. However, those of us who have participated in this exciting process do not delude ourselves into thinking that we have arrived at a final answer. The interim document we have produced will need further revisions and adjustments. But it does constitute a significant effort toward making possible greater participation by our membership in the affairs of our Association and as such is an important developmental step in our continuing revolution.

As a final comment about our internal APA structure, I must express my deep regard and warm appreciation to our Medical Director, Melvin Sabshin, and the entire APA Central Office staff. I have never met a more dedicated, harmonious group of individuals anywhere; the work of this Association could not begin to be accomplished without the efforts that they continually make above and beyond the daily demands of duty.

EXTERNAL RELATIONSHIPS

Turning now to our external relationships, one of the major issues that has preoccupied us in recent years has been the imminence of some form of national health insurance and our concern that such a program might not include adequate psychiatric coverage. At this juncture it does not seem likely that a national health insurance bill will be passed this year. Nevertheless, our efforts to provide our legislators with some of the hard data that they are looking for have met with partial success in that all bills now under consideration in Congress include some degree of mental health coverage. Our goal is to achieve equal and nondiscriminatory coverage for mental disorders, and we are persevering in efforts toward that end. With the help of the late Louis Reed and of Evelyn Myers and Patricia Scheidemandel of the APA staff we have been able to present data indicating that with essentially unrestricted health insurance coverage, mental health costs tend to level off at about 7% of total medical expenditures. We believe, therefore, that such coverage is not only actuarially feasible but also economically desirable, particularly if we bear in mind the direct and indirect costs of failing to cover mental health services. We are fortunate that our incoming President is unusually well informed about these matters, and I am confident that Robert Gibson will contribute significantly to our continuing efforts in this area.

We have also been concerned that such programs should not discriminate, as some presently do, against the private practitioner of psychiatry. We are convinced that the mental health needs of the American people will best be served by a pluralistic approach to the delivery of mental health care. I was pleased to participate during this past year in a national study of private psychiatric office practice, conducted under the auspices of the Joint Information Service of the APA and the National Association for Mental Health (1). This study called forth from Senator Edward M. Kennedy a comment that the data presented in it would allay the fears of those who have been haunted by the spectre of the catastrophic costs of private psychiatric services and will make it possible "to write a better coverage of private psychiatric care into national health insurance proposals" (1, p. 152).

The ultimate arrival of national health insurance will of course bring new challenges and responsibilities to our profession, and we are in the process of tooling up for them now. The key concept with which we must come to grips in the days ahead is that of accountability. The public is justly demanding this of all professionals and legislators alike. For us this means issues such as peer review, the preservation of confidentiality, questions of certification and recertification, continuing education, and the maintenance of high ethical standards. The officers of your Association, in coordination with the APA Central Office, have continued to pursue each of these areas vigorously. It should be noted, however, that these issues involve more than just encoded standards or external constraints on our ability to practice our profession. In the final analysis there can be no substitute for a high sense of *internal* responsibility that impels us to want to do our very best for our patients. Roger Masters and William May, in a recent issue of the *Hastings Center Report* (2, 3), both commented on the denigration of medical practice when it is treated—as it is more and more coming to be treated by our courts and by certain segments of the public—as just a contractual arrange-

ment between patient and physician. As May cogently put it, such an approach "reduces everything to tit-for-tat; do no more for your patients than what the contract calls for; perform specified services for certain fees and no more." What gets lost in this approach is what May called "the sense of covenant"—the feelings of mutual obligation, concern, and trust between patient and physician that transcend legalistic considerations. If these are lost then surely both we and our patients will be the poorer for it.

Given such a sense of covenant, the obligation that we all have to keep up with the rapidly expanding frontiers of knowledge in our field becomes an internal as well as an external mandate. I am particularly pleased that this year we have begun an important new program of continuing education in our convention proceedings, with 24 special courses being presented on a wide variety of topics. The overwhelming registration for these courses indicates that this program has evoked a strong positive response from our members, and it is my hope that the courses will become a permanent feature of our annual meeting and will be expanded even further in the years ahead.

Another important area of our external relationships is our effort to serve as an "ombuds-organization" on behalf of the mentally ill in our country. The Commission on Judicial Action of the APA, under the exemplary leadership of Alan Stone, has played an increasingly important role in this area of our activities. We are particularly concerned about the increasing trend toward governmental and judicial intrusion into areas of therapeutic judgment that we consider to be purely matters of medical responsibility. We believe this intrusion, however well motivated, is not in the best interests of the patient. We try to intervene selectively in situations where we feel that the issues are major, and we have had the satisfaction of knowing that in most instances our amicus curiae briefs have been quite influential.

The problem of the chronically mentally ill and of providing them with satisfactory hospital care as well as good aftercare continues to trouble us greatly. One of our major concerns in this area has been to protect the right to treatment of these patients and to put the responsibility for providing them with more adequate care where it belongs—on the shoulders of the legislative bodies that determine mental health funding, rather than on the psychiatrists who work under great difficulties and handicaps in understaffed and underfinanced facilities. It is true that psychiatrists in general have not placed a high enough priority on working in the institutions that treat the chronically mentally ill, but this is at least in part a consequence of the fact that opportunities for doing the kind of work that would be mentally and emotionally rewarding are lacking in so many of these facilities. This issue of the care of the chronically mentally ill will be explored more fully during the coming year in a special APA conference that is being organized under the direction of John Spiegel.

Still another basic issue confronting our profession is that of the conflictual role of the psychiatrist in situations where his therapeutic responsibility to the patient clashes with certain institutional demands. This issue is particularly distressing with regard to the psychiatric treatment of political offenders in the Soviet Union, but it is by no means confined to that country. In our own nation, as well as in others, such conflicting role demands are confronted by psychiatrists working in military organizations, mental institutions, prisons, schools, and the legal system, as well as other settings. Toward the goal of exploring the ramifications of this important and troublesome problem and possible solutions to it, we are in the process of organizing an interdisciplinary conference of experts in this area; we hope it will convene late this year or early next year.

We have persevered in our efforts to maintain communication with allied professions in the mental health field throughout the past year. Periodic meetings have been held with representatives of clinical psychology, social work, and psychiatric nursing, together with the National Association for Mental Health (representing the public). Although progress has sometimes been slow, we consider it of great importance to persist in the attempt to more clearly delineate our respective areas of professional responsibility. We are firmly convinced that there are areas in the field of mental disorder where the training of the psychiatrist is indispensable. The prescribing of medication and the ruling out of organic factors can be done only by someone who is medically trained. On the other hand, once it is clear that only psychotherapy is indicated, it would go contrary to logic and experience to insist that psychotherapeutic help cannot also be adequately given by the properly trained clinical psychologist, psychiatric social worker, or psychiatric nurse. We expect, however, that these allied professions will take the same kind of steps we have been taking to maintain high professional and ethical standards through continuing education, peer review, certification, and recertification.

Our concern with the attacks to which our profession has been subjected has led us during the past year to transform our Committee on Public Information into a Joint Commission on Public Affairs, reporting to both the Board and the Assembly. Ultimately it is hoped that this joint commission will develop a network similar to our government relations network that will enable us to coordinate our efforts and deal promptly at both the local and national levels with issues affecting the public image of our profession.

Finally, we have continued in the past year to maintain and foster our international relationships with colleagues in other countries. The APA, together with the Australia-New Zealand College of Psychiatrists, jointly sponsored the First Pacific Conference of Psychiatry last year in Melbourne, Australia; about 40 nations from around the Pacific basin participated. It was a successful and fruitful meeting, and we look forward to the next one, scheduled for 1980 in Manila. We are

hosting the Sixth World Congress of the World Psychiatric Association in Hawaii late next summer, and we are also cosponsoring the meeting of the World Federation for Mental Health that will be taking place in Vancouver a week earlier.

THE THEORY AND PRACTICE OF PSYCHIATRY

I turn now to the scientific development of our discipline. Compared with most other medical specialties, psychiatry has often been considered vague in its theories, imprecise in its practices, and unpredictable in its therapeutic effects. I believe it is fair to say, however, that enough advances have been made in all three of these areas in recent decades to justify our claim to be accepted as an equal partner with other medical disciplines in the corridors of science. For much of this twentieth century, psychiatry was strongly influenced by the theories and practices formulated by Sigmund Freud. During the thirties, forties, and fifties the impetus of psychoanalytic insight indeed brought a fresh sense of vitality to our field. It constitutes no disrespect to Freud's genius, however, to state that some of his theoretical concepts and therapeutic precepts have been superseded by newer understandings and developments in the behavioral sciences. Sexual or libidinal needs are no longer viewed as the primary sources of human motivation, nor are sexual frustrations or conflicts seen as the major sources of mental disorder, although their importance is by no means discounted.

The emphasis in contemporary behavioral therapy is on *growth and adaptation*—on how the organism from its earliest life adapts to the signals or stimuli that it receives both from within and without. The process of adaptation is seen as a continuous one, each developmental period building on the information and models acquired in the earlier ones. Psychological developmental periods are now seen as depending not on shifts of hypothetical libidinal energy from one erogenous zone to another, but rather on the sequential way in which the growing organism achieves more complex patterns of coordination, cognition, emotion, and psychological model building. Instead of instinctual drives seeking tension release, we now think in terms of inherited organ systems that mediate various behavioral patterns. The activation and inactivation of these inborn behavioral systems occur through neurohumeral mechanisms, the complexity of which is gradually being clarified and understood. The central nervous system functions as a dynamic cybernetic apparatus guiding and controlling behavioral reactions by a continuous process of information feedback from within and without the organism. The brain is seen as a spontaneously active organ that receives and integrates these data and transmits signals, rather than energy, to initiate actions and reactions.

Another major change that has been taking place in psychodynamic thinking has been a shift from the essentially closed system of the individual psychoanalytic model to an open system model in which the individual's functioning is examined in the context of his total group or field situation. As a consequence, the locus of psychopathology is no longer sought solely within the psyche of the individual but rather in his total system, encompassing biological and genetic determinants as well as his familial, group, and community relationships.

Considerable advances have been made in the last several decades in the understanding of the biochemistry of the neuroregulatory agents of the central nervous system. Interdisciplinary research between psychiatric clinicians and biochemists has given strong indication that metabolic derivatives of these neuroregulatory agents, particularly the catecholamines and indoleamines, may play a significant role in the pathogenesis and pathophysiology of schizophrenic and affective disorders. The answers are still far from definitive, and intensive research continues. But we do know that some of these metabolic by-products are capable of causing hallucinations and facilitating delusional states and that others clearly affect mood states. We know that their production is influenced by stress but also that genetic predispositions play a role. Thus, present indications point in the direction of an interplay of genetic, biochemical, and psychosocial factors in these major psychiatric disorders. It may well be that schizophrenic and manic-depressive patterns of behavior, and perhaps others also, are triggered by adverse and stressful interpersonal experiences in individuals who are susceptible due to genetically determined biochemical abnormalities in their neuroregulatory processes.

There have been important biological advances in many other areas also—in sleep research, in circadian rhythms, in genetics, in mental retardation, in the biological basis of memory and learning, in biofeedback and the control of involuntary functions, in infant and child development, and in the psychology of aging. However, in the interest of time I shall move on to another facet of our evolving field, namely, the revolutionary changes that have been taking place in psychiatric treatment methods.

The modern mental hospital has changed so markedly from its predecessors that it is hardly recognizable as part of the same tradition. Open doors instead of locked ones on most units, patients involved in various recreational and occupational activities and group meetings instead of interminably polishing gloomy ward floors, bright and cheerful rooms and lounges with curtains on the windows and pictures on the walls instead of barred windows and dark, cheerless hallways—these and many other contrasts illustrate the enormous strides toward a more humane and rational therapeutic milieu that have taken place over the past several decades in American psychiatry. Equally importantly, the biochemical advances to which I have referred have made possible certain pharmacological therapies that have strikingly reversed the need for

long-term mental hospitalization in many instances. In the schizophrenias, the depressions, and the manic disorders, these new pharmaceuticals have dramatically reduced the length of hospital stays for many patients from months or years to periods ranging from two to four weeks for most of them. Reflecting this change, the number of patients in state and county mental hospitals in the United States has dropped significantly in the past 20 years despite an increased rate of admissions and a rise of 20 million in the general population.

This is not to imply that these patients are all leaving the hospital "cured." After their discharge from the hospital, many will continue to require treatment in outpatient facilities or transitional settings such as halfway houses or day centers, of which, incidentally, we do not have nearly enough. Under such conditions, however, they are more likely to maintain family ties, participate in social and community life, and return to some level of economic productivity. Moreover, the medication that they continue to receive renders them more amenable and accessible to the ongoing psychotherapeutic efforts that are often necessary to enable them to cope with the stresses that may be present in their life situations. As Gerald Klerman cogently demonstrated in a recent study (4), psychotherapy and pharmacotherapy in such cases, far from being contradictory techniques, are complementary and mutually reinforcing.

Parenthetically, one area in which we are still woefully deficient is that of work therapy for hospitalized and posthospitalized patients. Although occupational therapy as presently available is useful, there is strong evidence to suggest that providing meaningful work, with compensation, would contribute more effectively to the social and psychological rehabilitation of many patients. In this respect we are far behind some of the Eastern European countries, but of course our economic system does not lend itself as easily as theirs to this kind of environmental manipulation.

Equally dramatic changes have taken place in the patterns of outpatient therapy. The recognition by contemporary psychiatry of the fact that psychopathology resides not simply within the individual but in his disturbed system of relationships has led to a considerable broadening of the parameters of psychotherapeutic practice. Although individual one-to-one psychotherapy still constitutes the most frequently used modality, there has been increasing emphasis on trying to deal also with the larger systems of the patient's interpersonal relationships. Thus there has been a growing utilization of conjoint marital treatment, family therapy, and group therapy, as well as efforts to modify other pathogenic aspects of the patient's life system wherever this is indicated and feasible.

Psychotherapy is now recognized as more than just a matter of giving a patient "insight"; it is seen as a learning experience by which the patient acquires new and more adaptive models of behavior, thinking, and feeling. The recognition of this has led to a renewed interest in various theories of learning and to efforts to apply these theories more effectively in altering the patient's maladaptive coping patterns. We have come to understand that therapy is not only a matter of the patient's unconscious preconceptions and transference distortions, but also that the real personalities of both patient and therapist—including such factors as intelligence, empathy, genuineness, value systems, and ability to relate to one another—are of major significance in the treatment process. As a consequence, psychotherapists are becoming more active participants in a dynamic transactional relationship with their patients.

Utilizing these various principles and awarenesses within the framework of insight-oriented and behaviorally oriented therapies, as well as combinations of the two, we have evidence that our psychotherapeutic efforts are becoming more effective and more economical in many areas. Patients with phobic disorders and anxiety states can often be helped within months instead of years, and the therapy of sexual dysfunctions, which once covered years and brought only indifferent results, can frequently be conducted successfully within weeks. Techniques of crisis therapy, brief or less frequent psychotherapeutic interventions, and group therapies have made effective psychiatric assistance economically available to larger numbers of people than ever before. Of course there are also serious personality disorders—analogous to some chronic medical disorders—whose roots extend into the earliest years of childhood; the therapy of these disorders still poses great difficulties and may require many years of effort. On the other hand, if we can catch such disorders in childhood, *in statu nascendi*, treatment of the disturbed family dynamics that foster them can often produce quick and dramatic changes for the better.

However, there is no room for complacency in any area of our field. Much remains to be done, and the effort must be a continuing one. In this regard we are deeply concerned about the low priority and the budgetary restrictions that recent administrations have been placing on mental health research, training, manpower, and services. We consider this approach to be exceedingly shortsighted and one for which our nation is paying dearly in economic terms as well as in human suffering. We shall continue to protest these cuts with all the vigor at our command.

THE CONTEMPORARY SOCIAL SCENE

I turn now to the fourth aspect of my comments. I have placed considerable emphasis on the developments that have been taking place in the areas of neurophysiology, neurochemistry, and psychopharmacology. But I would like to add a word of caution: we must not allow our growing awareness of the biological component in mental illness to lead us to a depreciation of psychodynamic and sociocultural determinants. Causality is hardly ever lineal and almost always multifactorial. The expectation, so often

cultivated in the news media, that some day all mental illness will be curable by drugs is a simplistic fantasy that fails to take into account the multifactorial elements in the genesis of mental illness. Our efforts at the primary prevention of mental disorders (an area, incidentally, that deserves far greater attention and research support than it has been receiving) will always have to be made on a variety of fronts—genetic, biochemical, familial, interpersonal, and sociocultural. We have long been aware of the deleterious effects that poverty; protein deprivation and other nutritional deficiencies; unemployment; racial, religious, and sexual discrimination; and other sources of social and economic stress can have on the mental health of individuals. There is no need to belabor this point to this audience, other than to point out that almost every APA President since Adolf Meyer has emphasized that these problems are a legitimate scientific concern for our Association, and that calling their deleterious effects to the attention of society does not constitute political action but rather is a reasonable exercise of our public health responsibility in the area of mental hygiene.

I would like now to focus on a somewhat different issue. Why do these detrimental conditions continue to exist in a nation so rich in scientific, technological, and natural resources 200 years after it was conceived in liberty and equality? Why is it, as we look around us, that we see so much moral corruption at all levels of our society as well as a pervasiveness of crime and violence that is rendering our urban communities increasingly unsafe and turning our homes into barricaded fortresses? Why has there been such a serious deterioration of shared and affiliative values and of common social purposes that the need to remain uninvolved has become far more compelling to most people than concern for their fellow beings? Society often turns to psychiatry for the answers to these questions, but although we can make pertinent contributions diagnostically, the treatment of these ills is beyond our competence alone. Problems such as these cannot be solved simply by improved child rearing or moral, educational, or psychotherapeutic practices. They are deeply imbedded in the very structure and fabric of our society.

Over 40 years ago Ruth Benedict, the noted cultural anthropologist, made an observation in her study of various cultures that I believe has some relevance to the issues I am raising (5). She observed that there was a very low level of intrasocial aggression and violence in societies in which an individual by the same act served his own advantage and that of the group; she called these "high synergy societies." The social institutions in these cultures were so constituted that what benefited the individual also benefited the group; thus mutual cooperation was encouraged and intrasocial competitiveness tended not to develop. In contrast, in societies structured so that the advantage of one individual was generally at the expense of another, intrasocial competition was fostered and a much higher incidence of intrasocial aggression and violence ensued. Dr. Benedict designated these as "low synergy societies." It is important to note, she pointed out, that the absolute amount of wealth in these societies was not the determining factor in the emotional security they did or did not afford: What counted was whether the economic system tended to concentrate the society's riches within a small group or to disperse them widely.

Although ours is an infinitely more complex culture than those Dr. Benedict studied, I believe her findings may well have applicability for us also. Ours is an essentially low-synergy society whose institutions for the most part require us to compete against one another to acquire its material and social rewards. Our basic personalities are shaped in the matrix of those needs, and adaptive success is usually related to the capacity to compete effectively, with what we have come to call "healthy aggression." But as our society has evolved, even though our per capita wealth continues to rise there has been a progressive maldistribution of this wealth, with a widening gap between the extremely affluent and the rest of the population. The rising rates of crime, violence, and moral corruption that we see around us may well be an offshoot, at least in part, of this maldistribution and the unconscious as well as conscious aggression and counter-aggression it stimulates among the "haves" as well as the "have-nots." This is not to discount in any way the importance of other factors such as personal psychopathology, TV violence, media coverage, and many others, but only to point at what may well be a fairly basic determinant.

It would be naïve to underestimate the enormous complexity of the issues involved or the difficulties inherent in trying to solve these problems. Arnold Rogow commented in his recent book *The Dying of the Light: A Searching Look at America Today* (6) that what is needed, among other things, is a massive redistribution of our wealth to end both poverty and indulgence, as well as an allocation of our capital and productive capacities to public rather than private demands. In my own thinking about this problem I have elsewhere suggested that a possible high-synergy direction in which our society might move would be to evolve broad patterns of cooperative social organization while maintaining the values of the free enterprise system in areas that do not involve the exploitation of natural resources or control over basic means of production (7). Needless to say, in striving for higher social synergy we must not under any circumstances sacrifice the precious heritage of human freedom that was given us 200 years ago.

It is earnestly to be hoped that in the years ahead leaders will emerge on our national scene capable of stimulating the kind of shared values that will restore a sense of unity to our nation and put us back on the high road of social progress that the founders of this nation dreamed of 200 years ago. Our country desperately needs restructuring of its priorities and revitalization of its purposes—not toward more horrendous weap-

ons of destruction but toward the betterment of human life.

As I bring these remarks to a close I cannot help reflecting briefly on how indebted I feel to the profession of psychiatry that I embraced more than 40 years ago. Although it has been the target of increasing criticism, I believe this is a reflection of its growing, rather than its declining, influence. The nature of our work tends to place us in loco parentis, and as parent surrogates we arouse unconscious expectations in others, who endow us with qualities of omniscience and omnipotence that we cannot possibly fulfill. Over and above this, like any other group we have our share of incompetent and poorly principled individuals. But, taken as a whole, I know of no other profession that is basically more dedicated to the enhancement of human dignity and reason, and the furtherance of human welfare, than is ours. Nor do I know of any endeavor that is more rewarding—not in the sense of material gain but in terms of personal enrichment—that not only gives us the precious privilege of helping other human beings in distress but also of learning from each of them so that our emotional growth and our vistas of understanding and compassion are progressively enhanced with each passing year, and in the end we can truly say with the ancient poet that nothing human is alien to us.

These past two years in which I have had the privilege of serving as President-Elect and as President have been particularly meaningful and gratifying to me. In my travels across the country I have been warmed by your hospitality and enriched by exchanging views with many of you on a wide variety of subjects. I have come to appreciate more deeply than ever the diversity of the threads that make up the complex fabric of our profession and to recognize that truth is a coat of many colors. I have viewed my task as that of integrating this diversity, to the best of my ability, in the common interest of all. If I have failed in any respect it has surely not been for want of trying! I thank you for the honor you have accorded me.

Response to the Presidential Address

BY ROBERT W. GIBSON, M.D.

ON THIS OCCASION of the 200th anniversary of our nation, it is particularly appropriate that Dr. Marmor in his Presidential Address has provided us with an overview of our Association's internal and external relationships, the theory and practice of psychiatry, and the relationship of psychiatry to contemporary America. This is fitting not just because it is the 200th anniversary of our nation, but because in all these areas we face major challenges and simultaneously have unparalleled opportunities.

It is characteristic of Dr. Marmor that he has said very little about his own role in the events of the past year. He has been an active President, an articulate spokesman, an able executive. It has been a privilege to serve with him and to experience firsthand the sensitivity of his guidance and leadership.

An outstanding example of this occurred in his tireless efforts to respond to the recommendations of the Key Conference. Dr. Marmor spearheaded the effort to develop a new organizational model and to create a new Constitution for our Association to implement this model. The deliberations included diverse points of view. They were frequently emotionally charged, and the obstacles often appeared insurmountable.

At times we seemed on the horns of a dilemma. Failure to act could be interpreted as resistance by the Board of Trustees to shift power to the Assembly of District Branches. To move ahead without thorough analysis of the complex checks and balances, to neglect the financial implications, or to ignore the legal consequences would be irresponsible. Dr. Marmor focused on these issues. He persistently reminded us of the need to increase the involvement of our members and to democratize the decision-making process. By so doing he made it possible for us to reach consensus and to submit a revision of the Constitution and By-Laws to the Secretary just days before the deadline. For this we are all indebted to him. A final resolution has not as yet been achieved, however.

At the meeting of the Board of Trustees on May 9 a decision was made to withdraw the version of the Constitution and By-Laws that had been submitted by the Board. This decision was reached after very careful deliberation and reflects the judgment of the Board that the document that had been prepared had serious faults. As a consequence the Board of Trustees is not formally submitting a new Constitution and By-Laws to the membership at the business meeting on May 11. Four previously prepared petition proposals are to come before the membership at the business meeting. In submitting these several proposals it was the intent of the petitioners to offer a range of options that could be subjected to further study.

A joint committee of the Board of Trustees and the Assembly will continue to work on a new Constitution and By-Laws, will carry out a critical review of all of the proposals that have been prepared to date, and will strive to prepare an improved version of the Constitution and By-Laws that will fulfill the recommendations of the Key Conference. I recognize the difficulty in grasping the full implications of these actions because of the complexity of the issues. I will do all in my power to clarify and simplify this material so that it may be presented to the membership in an understandable form.

There can be no doubt of the dedication and sincerity of the effort that has already been made. But in creating a new instrument to govern our Association for years to come we must be sure that it will be effective and will meet the many complex demands. In the interim as your incoming President and in collaboration with the Speaker of the Assembly of District Branches, I will strive to achieve the intent of the Key Conference recommendations: to shift authority for formulation of policy toward the Assembly and to seek increased involvement and participation of our total membership. This could be accomplished, in the period before a new Constitution is developed, through delegation by the Board to the Assembly of its authority over functions of the Association in such areas as education, mental health services, national affairs, emerging issues, and membership matters.

Dr. Marmor's description of the scope of the activities of our Association highlights not only the enormous expansion but the increased complexity of the many organizational components and staff. I suppose there was a time when it was enough for a professional organization to identify problems, to seek solutions, and to develop reasonable plans that would further the interests of both the patient and the profession. Now we are confronted by a multitude of demanding tasks. It takes constant effort just to identify the problems. We must be constantly vigilant to keep informed of developments in psychiatry, in medicine generally, in the overall health field, and in many

Presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

Dr. Gibson is 105th President of the American Psychiatric Association. He is Medical Director, Sheppard and Enoch Pratt Hospital, Towson, Md. 21204.

related areas. We must analyze this information so that we can formulate effective responses. We must anticipate problems so that we can take the initiative. We must maintain communication with the members to get the benefit of their wisdom and explain our actions, and we must learn the skills and mobilize the resources needed to get our recommendations accepted.

ADVOCATE FOR THE MENTALLY ILL

The APA is a scientific organization; about that I have no question or reservation. Yet the myriad activities described go far beyond the scope of medical practice and scientific inquiry. Simply collecting scientific data is not an end in itself. We already know far more about psychiatric treatment than is being effectively utilized. We must use that knowledge to make a difference—to benefit our patients. We have a responsibility to serve as advocate for the mentally ill. Dr. Marmor has given us a glimpse of the many fronts on which we move: government relations, judicial action, health care financing, public affairs, interprofessional liaison, advocacy for the underserved, to name just a few.

Dr. Marmor accurately portrayed the transformation of the mental hospital from snakepit and warehouse to therapeutic community. And he has emphasized the emergence of a continuum of treatment settings with varying levels of care from inpatient to halfway house, to day hospital, to emergency and crisis clinic, to outpatient care. All of these can be provided under public and private auspices, by the private practicing psychiatrist, and in organized settings.

However, what Dr. Marmor describes is what can be, what should be, the optimal. It is what patients must receive if this country is to make good on the commitment that adequate health care is a right and not just a privilege. It is what patients could receive if equal coverage were provided for the mentally ill under all systems of financing. Regrettably, in too many instances health resources that would permit the level of treatment that Dr. Marmor has described are not being made available. This is particularly true for the chronically ill, whose needs will be explored during the coming year at an APA conference.

The growing demand for accountability from all facets of our society has been especially stressed. Traditionally, professions have had society's sanction to govern the activities of their organization and their members. Indeed, this privilege is the hallmark of a true profession. In the past decade we have experienced an erosion of the public trust in virtually all of the institutions of our society. Comments such as "Health care is too important to be left in the hands of doctors" have become all too common.

As Dr. Marmor has pointed out, health is influenced by many social forces; psychiatry interacts with a multitude of systems. Such increased exposure inevitably opens us to new challenges and to demands to justify our practices. Endless harassment by regulatory agencies is the order of the day. We do not want our profession to be stifled by bureaucratic intrusions. This would be counterproductive to the best interests of patients. Yet we seem to be drifting in that direction.

All this generates anger and resentment, but simply protesting will not alter the course of events. In my judgment we must take positive and constructive action. I agree completely with Dr. Marmor that the public has the right to expect accountability not only from us but from all professionals and legislators, and I agree that in responding to these demands we will be involved in a broad range of activities, including peer review, preservation of confidentiality, certification and recertification, continuing education, and maintenance of ethical standards.

A PROFESSION WORTHY OF THE PUBLIC TRUST

As physicians we want to improve the quality of health care and we want such care to be available and accessible to all. To do so we must strengthen and refine our internal system of review to keep pace with advances in psychiatric practice and the increasing complexity of the delivery system. We must press ahead to define more clearly our own standards and criteria for what constitutes quality psychiatric care. Beyond that we must develop mechanisms to utilize our findings to improve all elements of our professional activity. We must demonstrate that our own voluntary system of peer review and quality assurance is more effective than the external requirements imposed by government and third-party payers. In short, we must reaffirm our stature as a profession worthy of the public trust.

Judd Marmor, M.D.
One Hundred and Fourth President, 1975–1976

BY MELVIN SABSHIN, M.D.

DURING THIS PAST YEAR the American Psychiatric Association required a President with an abundance of wisdom, graciousness, tact, good humor, energy, incisive intelligence, and tolerance, tempered by a capacity for the appropriate employment of forcefulness and limit setting. That our 104th President, Judd Marmor, possesses these characteristics among other qualities of leadership was exceedingly important when one considers the complexity of the decisions required in 1975–76.

It has been Dr. Marmor's singular burden and task to moderate the debate that has attended the process of determining whether we will adopt a new constitutional structure for the Association, based on the Key Conference consensus that the governing powers of the Association should be shared by the Assembly and the Board of Trustees. Our final decision, of course, remains to be determined by the voting membership. However, thanks in large part to Dr. Marmor, we may be sure that the basic questions related to the proposed structural changes have been explored, and our final vote can therefore be more informed and intelligent. Throughout, the debate over the question has engendered much affect, strong positions pro and con, a multitude of shadings of opinion, and withal an ever-present and deep concern about the future direction of our organization.

Dr. Marmor's mettle as presiding officer in many of the discussions was tested to the full. Whatever the ultimate decision by the membership, the process was facilitated by our President's basic conviction and faith that by fostering exchange and dialogue, by listening long enough to each other, by encouraging the expression of all possible points of view, it is possible to elicit a commonality of interests and to achieve an orderly process of change for the better. Clearly, it is leaders of Dr. Marmor's genre who provide the glue that holds our Association of 22,000 psychiatrists together in common dedication to advancing the objectives of APA.

To present a succinct but personal commentary about our Presidents in the relatively few paragraphs that are allotted every year in these pages is no small challenge. Obviously it is possible to select only a few highlights, and that is what will be attempted here.

Dr. Sabshin is Medical Director of the American Psychiatric Association.

The author consulted a number of sources in the preparation of this article; he would like particularly to acknowledge the assistance of Alex Rogawski, M.D. (1, 2).

EARLY YEARS

We begin by noting that Dr. Marmor was born in London, England, in 1910, the middle of three sons in a family of meager means but considerable intellectual accomplishment and a politically liberal orientation. His father was a writer, historian, and literary critic. When Judd was about a year old the family moved to Chicago, where his father became the Chicago editor of the Jewish *Daily Forward*. Judd spent his grammar school years in that bustling metropolis. In these early years his older brother was a promising student of literature. He had just graduated from the University of Chicago at the age of 20 when he died. This tragedy led to a depression in Judd's mother, to whom Judd was very deeply attached, and she began a pattern of relying heavily upon him. One might venture to suggest that the resolution of this poignant family crisis played a significant role in Judd's subsequent choice of career as well as his overall character structure.

Judd's education continued in New York City when his family moved to the nation's largest city and cultural center. Always a brilliant student, he graduated from high school at age 16 and did so well that he received two scholarships which, together with summer jobs, enabled him to attend Columbia University. Significantly, he majored in English there and read widely in the arts and humanities, with a special interest in Greek drama. His decision to become a physician was fortunate for us, given the diverse possibilities and pathways open to him. As an honor student he was admitted to the Columbia University College of Physicians and Surgeons at the end of his junior year. He received his A.B. degree (and a Phi Beta Kappa key) in 1930 after completing his first medical school year, and his M.D. in 1933. In his second year of medical school he visited a mental hospital and became "tremendously involved with the patients," as he puts it. That involvement fused with his interest in the humanities and science and his personal experiences into a decision to enter psychiatry. For Judd to opt for psychiatry in the climate of the early 1930s required the kind of passionate conviction and courage that so characterize him.

Promptly after graduation he was fortunate enough

to secure an internship at St. Elizabeths Hospital in Washington, D.C., where Dr. William Alanson White was Superintendent and Dr. Nolan D.C. Lewis served as Clinical Director. Dr. White was one of the leading early advocates and popularizers of psychoanalysis in the United States, and Dr. Lewis shared that perspective. Judd was already psychodynamically oriented and had been stimulated as well as fascinated by his extensive and intensive reading of Freud's collected works.

In 1935 he returned to New York City and took a neurological residency at Montefiore Hospital, where he was part of a milieu that attracted a number of bright young psychiatrists. Subsequently he applied for psychoanalytic training at the New York Psychoanalytic Institute. His application was readily accepted. In order to finance his psychoanalytic training he took a job at Brooklyn State Hospital at a salary of $2,000 a year, and at the same time undertook a personal analysis with Abraham Kardiner, also at a cost of $2,000 a year, leaving him nothing for "beer and pretzels." His days were full. He worked from 7:30 a.m. until 4:30 p.m. at the hospital. Then he dashed to the subway to go to his psychoanalytic hour. After that he grabbed a bite to eat, if he could manage it, and then saw two or three patients in the evening. He was lucky to get back to the hospital by midnight. Pragmatism finally prevailed and, at the age of 28, he gave up the job at Brooklyn State and took on more private patients. This relieved matters considerably.

The faculty at the New York Psychoanalytic Institute in the late thirties was a brilliant and exciting group featuring such luminaries as Brill, Spitz, Kubie, Lewin, Zilboorg, Stern, Horney, Thompson, and many others. These pioneers played a key role in the development of psychoanalysis in the United States; this included, of course, debate about theory, policies, and personalities. The departure of Karen Horney from the Institute aroused a great deal of passion and concern. Judd shared this concern and was critical of what he perceived to be a strong tendency toward orthodoxy and authoritarianism among the leadership of the New York Psychoanalytic Institute. He resigned from the Institute and joined the Horney group in the American Institute of Psychoanalysis only to find, to his disappointment, that some of the same problems of factionalism existed in the new setting. In part out of discouragement, he joined the faculty of the Department of Psychiatry at New York Medical College, where a new organizational structure for a psychoanalytic institute was being attempted. Later those involved in this endeavor joined with a number of other constituencies in organizing the American Academy of Psychoanalysis.

Happily, there was more to this period in Judd's life than career decisions and changing affiliations. In 1938, Judd married Katherine Stern—a joyous and felicitous event. In 1941 their son Michael was born. Now, 35 years later, Michael is Assistant Professor of Ophthalmology at Stanford, having already demonstrated a creativity and scholarship rivaling that of his parents. He and his wife, also a physician, are raising two children of their own.

We may safely assume that being the spouse of a dynamo like Judd is never easy. But Katherine has always made it seem comfortable, not only by her devotion to him but by also creating her own world of interests in contemporary art and the theater and sharing them with Judd. In addition, Katherine has complemented Judd's dedication to the mental health cause by receiving a master's degree in psychology and by assuming leadership in the group therapy program at the Los Angeles Suicide Prevention Center. Those of us fortunate enough to know Katherine Marmor have also learned of her warmth, her keen intelligence, and her sense of justice and dignity.

THE WAR YEARS

In World War II Judd joined the U.S. Public Health Service and was assigned to a Navy base in Florida near the base where Grinker, Spiegel, Donahue, and Weinberg were attached. Judd became acquainted with the Don Cesar Army Air Force Convalescent Hospital group in St. Petersburg, all of whom have became significant leaders in the American Psychiatric Association.

Happily, during the war he had an opportunity to reflect on his career thus far and to ponder what course he should take after the war. He made two major decisions. First, he would apply for readmittance to the New York Psychoanalytic Institute and hopefully complete his work there. He believed that he had probably made a mistake in leaving in the first place and that more could be accomplished by working from within to bring about constructive change. Second, after this was accomplished, he would move to California, where he would combine private practice with teaching, research, and community work. He achieved both of these goals. The New York Institute welcomed him back warmly and told him he would not have to undertake further personal analysis but would only need to have some additional supervision of his analytic work.

THE MOVE TO LOS ANGELES

Judd moved to Los Angeles in 1947 and completed his psychoanalytic training at the Los Angeles Psychoanalytic Institute in 1948, soon becoming a member of the American Psychoanalytic Association. Then, to his distress, he found himself once again in a "split" situation in the Los Angeles Psychoanalytic Institute in the early fifties. Judd again wanted no part of this factionalism and attempted to retain his membership in both the original Institute and the newly formed Southern California Psychoanalytic Institute. Ultimately he became a training analyst in the Southern California Psychoanalytic Institute and has remained a member

of this group to the present time.

Without ever intending to isolate himself in this single pursuit, he established a flourishing private practice in Los Angeles. His empathy with private practitioners is deep and is still present, as was reflected in the recent Joint Information Service volume on private practice (3).

Dr. Marmor became a Clinical Professor of Psychiatry at the University of California, Los Angeles, a Visiting Professor at the UCLA School of Social Welfare, and a consultant to the Los Angeles County Bureau of Adoptions (reflecting his growing interest in social psychiatry). He was also Senior Attending Psychiatrist at the Los Angeles County General Hospital and Mount Sinai Hospital and Senior Consultant at the Wadsworth Veterans Hospital. Later he was to hold other major appointments in the area, notably those of Director of the Division of Psychiatry at the Cedars-Sinai Medical Center and in 1972 Franz Alexander Professor of Psychiatry at the University of Southern California.

ROOTS OF HIS VALUE SYSTEM

Judd's deep distaste for anti-intellectualism, prejudice, and dogmatism in all their forms had its roots in his early upbringing in an intellectual family setting. As a youngster he was the only one in his class who supported Eugene Debs when he was running for President. He was much impressed by the essays of the agnostic Robert Ingersoll and the novels of Jack London. Upton Sinclair also greatly influenced him, especially Sinclair's *Cry for Justice*, which sparked Judd's natural impulse to fight for social justice. Like many others he was deeply taken with the concepts of dialectical materialism, which perhaps played a role in shaping his view of man as the product of many forces of action, reaction, and synthesis—a fitting intellectual precursor to dynamic psychiatry. Again, like a number of his contemporaries he became disillusioned with the application of Marxist dialectical materialism in the Soviet Union. Throughout his life he has been fascinated by theories but ever careful to escape from the ivory tower of an isolated theoretical construct. He has always been open to new observations and divergent opinions and has been willing to stand up to the displeasure of powerful groups for deviating from the rigidities of their beliefs.

PREDOMINANT THEMES

In the same year (1974) that we elected Judd our President, his major work, *Psychiatry in Transition* (4), was published. It contains what he considers his chief contributions to the literature over the past 40 years. As he himself explains, certain predominant themes pervade all of his contributions.

One is that if a theory fails to rest on sound scientific thought and yet proves itself pragmatically effective, then the theory, not the practice, must be altered. Psychiatry has always encompassed a myriad of approaches, virtually all of which work at times and fail at times. If we are ever to find a way out of the scientific maze, it will only be by clinging to the compass of scientific thought and method.

A related theme is resisting the siren call of simplistic or "linear" explanations of complex problems. One must rather turn to a general field or systems theory wherein the human being is viewed as an open system in which inner self-activating mechanisms and feedback processes are in continuous exchange of energy and information with the environment. Judd's recent papers on psychotherapy clearly reflect this perspective.

Still another theme is the search for common denominators underlying divergent views that characterize our field—a theme which applies aptly to his conduct as our President this past year. As Judd puts it, the biologically oriented psychiatrist seeks to explain human behavior primarily with biological determinants, the psychoanalyst in pure culture emphasizes intrapsychic factors, and the social psychiatrist views sociocultural causality as most significant. To Judd, any comprehensive explanation of human behavior must encompass all three vectors, not in sum, but in dynamic interaction with one another (4, p. xii). Beyond stating these principles abstractly, Judd lives and breathes these ideas and they affect his every paper, speech, and act of psychiatric leadership.

Finally, throughout all that he has done and thought is his overriding belief that the human condition can be bettered—that war and poverty must be eliminated, that social justice is achievable, and that human values can indeed change for the better. Judd is not a starry-eyed idealist and he recognizes the difficulties in achieving these ends, but the effort must be made in a rational and occasionally pragmatic fashion.

In addition to his compassion and his genuine warmth, Judd is extraordinarily eloquent. Not only are his writings edifying, but because of his clarity and economy of diction they are easy to digest. His artfulness in presenting complexities in crystal-clear and logically ordered sentences renders the most complex matters relatively simple to grasp. Moreover, as Eisenberg says in his introduction to Judd's book: "One of the most remarkable qualities of Judd Marmor's writing is the extent to which it has survived the usages of time. . . . The great majority [of chapters in his book] have focused on problems no less central to contemporary psychiatry than they were when the papers first appeared" (4, p. v). Eisenberg goes on to say that Judd is on the side of the angels and salutes him as one of the "happy few willing to do battle for the liberation of man's spirit." He continues,

> In the end, no reader can fail to sense the compassion, the perceptiveness and the heterodoxy of these collected papers. Their author has a point of view, but people come before theories. He is acutely aware of the struggles, the

> contradictions and the uniqueness of each of the troubled persons who seek his help. In responding to their needs, he refuses to be bound by what ought to be so and insists upon recognizing what *is* so. To his work, he brings a richness of experiences, a treasury of scholarship, a life committed to trying to be of help and humbled by an awareness of the limitations to even the best informed effort to meet that challenge. (4, p. vii)

An example of the survival value of his works is that Judd noted in 1955 that it was impossible to set down rigid rules about whether psychotherapy should be directive, nondirective, silent, talkative, reserved, or friendly, because the method would have to relate to the patient's needs. Further, it was absurd to think that the doctor's value judgments could be entirely eliminated from his relations to the patient. What was important was that the therapist, whatever method he used, enhanced the patient's growth and self-realization (4, p. 294).

In 1953 he pointed out that the constant exercise of authority by the psychotherapist carries with it the occupational hazard of tending to create unrealistic feelings of grandiosity and superiority in the therapist, and that this tendency fostered strong "in-group" feelings (4, pp. 280–282). This led to the development of a private language in the in-group and rendered communication among different groups more difficult. While personal analysis and supervision were helpful in alleviating these tendencies, they were not enough, and the therapist had to be constantly on guard lest he overestimate his own status and ideas. Only by cultivating "democratic" interpersonal relationships with a variety of people and groups could he guard effectively against "The God Complex" (Ernest Jones's phrase).

In 1955 Judd postulated his firm conviction that "ultimately we shall be able to extrapolate out of all the diverse and multitudinous approaches which are included under the broad concept of psychotherapy, those common denominators which are the specific therapeutic factors . . . [and] when we do, we shall find that the most significant factors lie not in the area of verbal interpretations made by our patients but, more importantly, in the area of interpersonal relationship between the therapist and the patient" (4, p. 293). If we can but use our present structures on which to build a truly scientific psychotherapy, he added, we may achieve the ideal of the psychotherapist which Nathaniel Hawthorne expressed so brilliantly in these words from the *Scarlet Letter*:

> If the [physician] possess native sagacity, and a nameless something more—let us call it intuition; if he show no intrusive egotism, nor disagreeably prominent characteristics of his own; if he have the power . . . to bring his mind into such affinity with his patient's, that this last shall unawares have spoken what he imagines himself only to have thought; if such revelations be received without tumult, and acknowledged not so often by uttered sympathy as by silence, an inarticulate breath, and here and there a word, to indicate that all is understood; if to these qualifications as a confidant be joined the advantages afforded by his recognized character as a physician—then at some inevitable moment, will the soul of the sufferer be dissolved, and flow forth in a dark, but transparent stream, bringing all its mysteries into the daylight. (4, pp. 294–295)

All of this provides only a suggestion of the flavor of Judd's thinking. Altogether he has contributed 175 scientific papers and four books to our literature.

AFFILIATIONS AND HONORS

The combination of his scholarship and literary skills has led him to the editorial boards of such journals as the *American Journal of Psychoanalysis, Archives of Sexual Behavior, Contemporary Psychiatry, Contemporary Psychoanalysis,* and the *American Journal of Community Psychology*.

His leadership abilities have also been reflected in his service on the boards of directors of the American Orthopsychiatric Association, the Behavioral Science Research Foundation, the Group for the Advancement of Psychiatry (which elected him president from 1973 to 1975), the Sex Information and Education Council of the U.S., the Human Action Research Foundation, and the Neumeyer Foundation, as well as several others. He served as APA Vice-President before becoming President-Elect.

Many of Judd's other roles, affiliations, and activities have been omitted, but it should be noted that he holds an honorary Doctor of Humane Letters degree from the Hebrew Union College in Los Angeles, was made an Honorary Fellow of the Australian and New Zealand College of Psychiatrists in 1975, and was given the Silver Medal Award by the Columbia University College of Physicians and Surgeons in 1967 for his distinguished contributions to the field of psychiatry.

In sum, Judd Marmor is a humanistic psychiatrist and scholar whose hopes and aspirations reflect many of the most positive values and ideals of a democratic society. Furthermore, he is an articulate and lucid spokesman in an age of increasing complexity. He will do still more, and we must be grateful that such a man has symbolized the image of our profession during his tenure as our President.

The Psychiatrist and the Pain Clinic

BY I. PILOWSKY, M.D., D.P.M.

The author discusses the difficulties inherent in the role of the psychiatrist in a pain clinic as well as some of the recurring problems that he has seen in this setting. He states that the psychiatrist brings to the understanding of pain a multidimensional approach, which is hard for nonpsychiatrist clinicians to accept, and valuable psychophysical methods for evaluating and quantifying pain. He discusses aspects of the interplay between intrapsychic and interpersonal factors in the pain experience, particularly the relationship between pain and guilt, and illustrates these aspects with case reports.

THE ROLE OF THE PSYCHIATRIST in a pain clinic may be variously defined, but in essence it involves the elucidation of the psychological and interpersonal factors contributing to the nature of the patient's pain experience and the planning of appropriate management in light of these factors.

Fulfilling this role is inevitably difficult; it seems profitable to consider briefly why this might be so and how the difficulty might be met. Having done so, I will describe a number of recurring clinical constellations and themes that have been seen in the clinic of which I am a member, in the hope that the theoretical and practical issues they raise will be of general interest.

DIFFICULTIES IN THE PSYCHIATRIST'S ROLE

It must be the experience of every psychiatrist who has accepted membership in a pain clinic that his first task is to persuade other members that he does not believe every pain to be "psychogenic." Achieving this is peculiarly difficult; the sources of the difficulty bear consideration.

In the first instance it must be acknowledged that in certain pain clinics the number of patients in whom psychosocial factors are the chief determinants of their pain experience is extremely high. Clinic members such as anesthetists, neurologists, and neurosurgeons are inevitably frustrated by such patients because they feel their cases offer little scope for expertise. Under these circumstances the nonpsychiatrist physicians are limited to the use of diagnostic procedures that exclude various pathologies but contribute little to therapy.

This is particularly true when most of the patients referred to the clinic have been thoroughly investigated for the presence of significant somatic pathologies before referral. On the other hand, it is rare to encounter a patient in whom the psychosocial dimension has been explored beyond the superficial level. Thus in virtually every instance the psychiatrist is able to make a major contribution to the understanding of the patient's problems and consequent management; often, in fact, the psychiatrist seems to provide all the answers.

It is important to realize that an understanding or, perhaps more accurately, a conceptualization of the patient's personality and current life situation is not to be equated with a knowledge of the etiology of the patient's pain—except in terms of the rather simplistic causal models used by many clinicians. Although most clinicians will acknowledge the fact that not all preconditions are either necessary or sufficient for the development of a particular disease process, they will in practice frequently speak of discovering "an organic cause for the pain." Similarly, one may find one's nonpsychiatrist colleagues only too eager to accept the idea that psychological factors explain the patient's pain entirely.

Clearly, then, the clinician has a deep need to find "the cause" or, more importantly, "the remediable cause," and rightly so. Unfortunately, however, unitary concepts have an exceedingly short half-life in the psychosomatic field, not that their inappropriateness prevents clinicians from applying whole series of treatments to patients with chronic pain in the hope that the jackpot will somehow be hit. Quite possibly it sometimes is, but the nature of the referral process to a pain clinic ensures that the psychiatrist on the panel will rarely if ever encounter such an outcome.

The factors contributing to the search for "the cause" are multitudinous, but of particular importance seems the tendency toward compartmentalization of medical training at both the undergraduate and postgraduate levels. For quite sound pedagogic reasons each teacher tries to sell not only his own wares but also the most clearly defined examples of them. In the time available it would be foolish to do otherwise, but the price must eventually be paid, because the vast majority of patients (particularly in the community setting) do not present problems that can be neatly pigeonholed.

Dr. Pilowsky is Professor of Psychiatry, University of Adelaide, Adelaide, South Australia, 5001.

The multidimensional approach is therefore not one that comes naturally to the clinician. His resistance to it may help explain his negative attitude toward the psychiatrist. It is part of the psychiatrist's task in the pain clinic to convey what the multidimensional approach entails and how it may be used. Simply stated, it is predicated on the assumption that the pain experience is shaped by a constellation of variables, which the clinician is required to identify and then rank in terms of the "size" of their etiological role and, perhaps more importantly, the degree to which they are amenable to therapy. It is also important to emphasize that various treatment programs can be initiated simultaneously. For example, the need to carry out further radiological investigations does not preclude the use of psychological and social treatment modalities.

In this context one should perhaps mention the use of admission to the psychiatric ward of a general hospital as a therapeutic and diagnostic tool. For cases in which etiologies are complex and the assessment of disability difficult, the psychiatric ward is particularly well placed to make a contribution to the assessment process. This is so because of the opportunities it provides for normal motor functioning: patients are able to dress, move about, and participate in a wide spectrum of activities against a background in which the impairment caused by the pain can be evaluated over a more extensive time period than is otherwise possible.

EVALUATING AND QUANTIFYING PAIN

The area of evaluating and quantifying pain is one in which the psychiatrist who has a background in psychological research, especially in the use of psychophysical methods, can be particularly helpful to a pain clinic.

In our pain clinic we have found visual analogue scales extremely useful as an adjunct to purely clinical methods of pain assessment. The scale we use consists of a 10-cm line, at the left-hand end of which are the words "I have no pain at all" and at the right "My pain is as bad as it could possibly be." The patient is asked to indicate the severity of his pain by making a mark on the line. The pain score is measured in millimeters from the left-hand end of the line. The advantages of this method reside in the fact that it can be used at frequent intervals, is simple to administer, and is complete. In this way a detailed, continuous picture of an individual's pain experience can be obtained.

Information of this sort can be of considerable importance in helping the patient and staff gain some perspective on the pain suffered by the patient. For example, it has allowed us to monitor pain throughout a nerve block and to observe whether the pain curve coincides with the curve expected, given the known pharmacokinetics of the anesthetic agent used. It is of interest that in some patients the pain disappears almost completely when the needle penetrates the skin and then proceeds to build up after the anesthetic agent is inserted. In others the curve is exactly as expected. In neither case, however, does the course of pain alleviation predict ultimate outcome.

In some cases the "pain line" can be used to monitor pain at hourly or less frequent intervals for days. With this approach it is not unusual to find that pain is not nearly so continuous or severe as the referring doctor's concern has suggested it might be. This type of discrepancy is extremely interesting and a not infrequent finding. In fact, the psychiatrist may discover that he is the first clinician in a long while to take a detailed pain history and to establish precisely the extent to which the pain interferes with the patient's usual activities.

When such a discrepancy is found it is often the case that some person other than the patient may be even more concerned about the pain than the patient himself. One patient who illustrated this situation was a 48-year-old factory worker who had injured his back in a fall. Although he was not completely well when seen, he showed considerable adaptation to his situation. His wife, however, was extremely concerned because a number of the men in her family had died after falls in the coal mines where they had worked. She was convinced that the same would happen to her husband. She was depressed and anxious about his condition and had persuaded him to seek help.

At other times the spouse may be important in a negative rather than a positive sense, in that the patient's pain may worsen when support is withdrawn because some stress has caused the spouse to seek rather than give support. A typical situation is one in which the spouse has experienced a loss, such as a bereavement, and has become depressed. The patient then experiences a worsening in a pain that may have been present for many years.

One may also find that the spouse also suffers pain. In some families it is clear that members compete with each other for the sick role in a manner that is faintly echoed in many well-adapted families from time to time.

Such cases underscore the particular importance of establishing whether the pain has altered in its nature or severity. Patients will often initially describe the pain as having been present for many years without drawing attention to any change in its character that may provide a clue to the etiological factors currently operating. If such a change in the clinical course is not appreciated, it may be concluded that the prognosis for improvement is extremely poor when in fact the patient can be helped to return to a reasonable level of functioning.

I have referred to the fact that a change in the patient's pain experience may be due to a change in the attitude of a spouse; it goes without saying that a change in the health of any member of the family may have a similar impact. I would also like to draw attention to a frequently overlooked "significant other" in whom a change may lead to an alteration in a chronic pain situation. I am referring, of course, to the

patient's physician. This is especially striking in elderly patients who have been cared for by the same physician for many years.

In one woman in her 70s who had experienced pain for at least 10 years the change came when she became aware that her aged family physician had suffered a coronary occlusion. She described extreme preoccupation with the possibility of his dying. Needless to say, careful inquiry revealed that the patient, a widow, had developed a powerful positive transference for the physician over the years, with the sort of sexual overtones most clinicians hesitate to perceive in the elderly. In this case it was important to help her discuss the realities of the situation and to deal with the ambivalent feelings that the threatened loss had aroused in her.

I am aware that in describing the role of the significant other I have focused on current interpersonal factors in rather general terms. A somewhat more detailed consideration of the interplay between intrapsychic and interpersonal factors in relation to their effect on the pain experience is obviously necessary. I propose to discuss a particular facet of this complex area.

PAIN AND GUILT

A number of authors (1, 2) have drawn attention to the relationship between pain and guilt. Nonpsychiatrists often question the role that guilt plays in the causation of pain and ask by what mechanism the former can lead to the latter. The question is a good one and has been posed with some force by Ziegler and Imboden (3) in their discussion of conversion reactions. In the case of pain syndromes I have found it simpler to consider whether a particular symptom "serves a conversion function" than to speak in terms of "a conversion pain." By "conversion function" I refer to the process whereby a physical symptom permits a patient to avoid conscious awareness of a particular conflict and the unpleasant affects accompanying it.

The interaction of guilt and pain illustrates this point well. Whatever else clinical observation may suggest, there seems to be a distinct tendency for guilt and pain not to coexist. The following brief case report illustrates this phenomenon rather dramatically:

Case 1. Mr. A, a steelworker in his 40s, complained of pain involving his penis and perineum that he had suffered for about 15 years. Despite the pain he worked extremely hard in a rather driven, compulsive manner.

He was admitted to a day hospital for assessment and, surprisingly, improved dramatically within about 10 days to the point where the pain was no longer present. He was discharged and seen in the outpatient clinic about 2 weeks later; at this time he complained of severe depression. He communicated these feelings rather histrionically and related for the first time the fact that he had persuaded his wife to fellate him regularly for many years and was overcome with guilt at having done so. On being reassured by the hospital physicians that his guilt was inappropriate and excessive, he said that his family physician (a woman) had already attempted to convince him of this but that he could not be influenced in any way.

He was admitted to the hospital once again. Over a period of 2 weeks his depression, which showed no obvious biological features of the psychotic type, gradually abated, and the pain returned. He was able to return to work and stated that he was finally convinced that his guilt, which had now subsided, had been excessive.

This patient's clinical course suggests that pain may serve to neutralize guilt and that it may be reasonable to generalize that in most individuals pain and guilt rarely coexist. When one considers that pain is almost universally equated with punishment and the expiation of sins it is not difficult to accept the idea that pain may play an important role in the achievement of psychological equilibrium, particularly in guilt-prone individuals.

The acceptance of a model of this sort does not require the existence of some special neurophysiological pathway that somehow links the experience of guilt with the genesis of pain. For most individuals there is, in the course of a lifetime, ample availability of physical sensations of one sort and another, any of which may serve a conversion function at some time. In fact, the conscious use of physical states to avoid unpleasant situations or feeling states is common.

If an explanation for the presence of a particular symptom at a particular time is required, then the well-demonstrated physiological correlates of emotional states would clearly offer a wide range of subjective sensations capable of fulfilling the conversion function. As far as pain is concerned, it is clear that the muscular tension that accompanies certain states of arousal, especially those associated with anger and anxiety, is particularly likely to generate pain at the somatic level.

Thus at the intrapsychic level it may perhaps be said that a quantum of pain neutralizes a quantum of guilt. What may we say at the interpersonal level?

My experience in a pain clinic suggests that although pain has a powerful communication value, its effect changes with chronicity. If pain neutralizes guilt in the patient, what emotions can the patient communicate under its protective cover? Pain gains for the patient admission to the sick role with all its attendant privileges and obligations, which include the duty to seek and use appropriate help.

The patient whose pain is associated with guilt over feelings of loss, anger, or dependency is able to make demands on and achieve closeness to a host of professionals, but the repeated presentation of pain complaints to clinicians who are unaware of their true significance and function inevitably evokes their anxiety, anger, and guilt. These responses may in their turn lead to covert and overt attacks on the patient. Covert attacks may include painful investigations and operations, and overt ones may involve quite frank castiga-

tion of the patient and the imputation of malingering, lying, or mental illness. A reaction of this sort on the clinician's part must inevitably result in a hostile response from the patient, coupled with fear of total rejection. In these circumstances the reporting of pain allows "retaliation by physical complaint" and the preservation of some self-esteem.

In this situation the pain clinic serves a very important function as a sort of sanctuary for both the patient and his clinician. In the clinic peaceful relations can often be reestablished, provided that the patient's hostility at having been referred is dealt with in the very earliest stages. Unless the inevitable negative transference is verbalized and resolved, its continued presence must militate against any further progress.

I have referred to the possibility that a clinician may not be fully aware of the significance of a patient's pain as a communication, nor indeed of the precise characteristics of the patient's pain experience. In addition, some patients do not communicate all of the circumstances of the onset of the pain. These circumstances may be so crucial to the understanding of the pain that the clinician is quite unable to assess the illness adequately. This is often seen in patients whose pain follows an accident that has become the focus of a claim for financial compensation. As might be expected, a number of patients referred to a pain clinic fall into this category.

In a substantial number of these cases a pattern emerges that casts a most interesting light on the negative reactions these patients so often evoke. The aspect of this pattern that appears central to me is the tendency for both the patient and the doctor to enter a tacit agreement or collusion not to explore with any degree of completeness the precise nature of the accident. A few clinical examples may serve to illustrate this point:

Case 2. Mr. B, a man in his early 40s, had suffered headaches since a mining accident 15 years before. As he first told it, the accident involved his being struck on the head by a hopper used for conveying excavated earth out of the mine shaft. He said he had not lost consciousness and, after a short spell in the hospital, returned to work, having sustained a fractured zygoma and little else.

Detailed questioning revealed a rather different picture. The descending hopper had in fact struck his head against a fixed steel railing and locked it there while gradually crushing it under its enormous weight. He remembered hearing the bones of his face cracking and wondering how much more he could take before his skull burst. Fortunately, a workmate managed to release him and he was moved to safety. It is not surprising that this experience produced a classic traumatic neurosis, with recurring nightmares and headaches occurring usually around the anniversary of the accident.

Case 3. Mr. C had been electrocuted while at work. At first he reported that the whole incident lasted a few seconds and that he remembered virtually nothing. In fact, however, he was able to recall on questioning that he had been physically stretched and extended by the shock and felt at the time that he was experiencing his own dying.

In the absence of this type of information, which patients often suppress because of the unpleasant affects it reactivates, the clinician cannot fully comprehend the impact of the accident on the patient. There seems to be a discrepancy between the injury and its sequelae, and the physician often conveys his skepticism to the patient, who in turn becomes resentful and complains with renewed vigor or refuses to cooperate at all. The unfortunate fact is that when financial compensation is an issue, the doctor-patient relationship tends to be deformed: the doctor tends to judge rather than diagnose and report rather than treat. Under these circumstances the management of pain is virtually impossible; every effort has to be made to resolve the financial compensation issue as soon as possible.

RARE CASES

Having described some of the issues that have been prominent in our clinic, it may be worthwhile to mention some that have been conspicuous by their relative rarity. The first concerns pain as a depressive equivalent. I do not wish to discuss this concept in detail except to say that the presence of pain (or any form of illness behavior) seems to modify the presentation of depression. However, we have encountered very few patients who seemed to be suffering from a depressive illness requiring definitive treatment. We obtained a highly satisfactory result by the administration of a tricyclic antidepressant in only one patient, who showed the typical biological features of depression. One cannot conclude from this that pain syndromes due to depression are rare. It may be that with the widespread use of antidepressants very few of these cases actually reach the pain clinic.

I have also not said a great deal about the use of neurosurgical and other techniques for the treatment of pain in patients with advanced cancer. This is because the numbers referred to the psychiatry service are not great—probably reflecting the sensitivity of our radiotherapy department to the psychological and social problems of their patients as well as their readiness to supply them with adequate quantities of analgesic agents.

COMMENT

Finally, I would like to make a general comment on patients taken for treatment by the department of psychiatry. The therapeutic methods used are, in the main, conventional. Psychotherapy and milieu therapy are important mainstays. Physiotherapy is regularly used and includes relaxation exercises, interferential treatment, and biofeedback, which incidentally helps to reinforce our assertion to the patients that all aspects of their illness must be tackled and allows them to relinquish the defensive use of somatic problems at a pace that is appropriate to their individual needs.

Patients who are receiving large regular doses of analgesics are gradually weaned with their active cooperation; we do not allow a power struggle to develop between patient and staff.

In our patients, prognosis and outcome are assessed not merely in terms of the amount of pain reported but also in terms of function. It seems important to emphasize this point because so often clinicians have difficulty accepting that a patient may have achieved homeostasis because of and not in spite of a certain amount of pain and that the constant presence of some pain and the offering of the pain complaint must be accepted as part of the patient's mode of existing and relating. In the words of Ugo Betti (4),

> Nothing is more dear to them than their own suffering—they are afraid to lose it—they feel it, like a whip cracking over their heads, striking them and yet befriending them; it wounds them but it also reassures them. (p. 57)

Follow-Up of Depressed Women After Maintenance Treatment

BY MYRNA M. WEISSMAN, PH.D., STANISLAV V. KASL, PH.D., AND GERALD L. KLERMAN, M.D.

The authors present follow-up results based on 150 women 1 year after maintenance treatment for depression. Maintenance treatment consisted of 8 months of amitriptyline, psychotherapy, or a combination of the two, administered by random assignment following recovery from an acute depressive episode. Approximately 30% of the patients remained in complete remission, 60% experienced recurrence of symptoms, and 12% remained mildly but chronically symptomatic. The implications of these findings for planning care for the ambulatory depressed patient on both an individual and a public health basis are discussed.

CLINICIANS and public health administrators planning for the care of depressed patients need to know something about the efficacy of treatments and the natural history of depression in order to plan long-term treatment programs. This information is beginning to become available in such longitudinal studies as the Boston-New Haven Collaborative Depression Project, in which a large sample (N=150) of depressed female outpatients were treated with amitriptyline, psychotherapy, or a combination of the two. The overall goal was to evaluate the place of maintenance therapy in the treatment of depression and to follow the patients after treatment ended. We were convinced that drug therapy had established its efficacy for the symptomatic relief of acute depression and that it was necessary to assess maintenance therapy to determine its effectiveness in preventing relapse and minimizing disability.

There were three phases of the study: acute treatment, maintenance treatment, and follow-up. The results of acute and maintenance treatment, reported last year, indicated that a substantial number of the patients who entered the acute treatment phase of the study and received amitriptyline for 4–6 weeks improved significantly within that time (1) and that 8 months of maintenance treatment was feasible, efficacious, and safe (2). Maintenance amitriptyline therapy prevented relapse and symptom return but did not have a differential effect on the patients' social functioning (3). Psychotherapy, on the other hand, did not prevent relapse or symptom return but did improve social functioning in patients who completed the trial without relapsing (4).

In this paper we will report follow-up results 1 year after maintenance treatment and look at the implications for planning treatment on both an individual and a public health basis. In cases when sustained effects of maintenance treatment could not be established, we examined the natural history of outcome, keeping in mind the variable course of depression.

RESEARCH DESIGN

The admission criterion for acute treatment was a Raskin Depression Scale score of 7 or more (5). Patients who entered acute treatment received amitriptyline in an open trial in dose ranges of 100–200 mg. Those who responded after 4–6 weeks of acute treatment (N=150) entered the maintenance phase, which took the form of a 3 × 2 balanced factorial design and was conducted at the Connecticut Mental Health Center (Yale University) and Boston State Hospital (Tufts University).

All patients were seen monthly by the initial treating psychiatrist in brief interviews for assessment and prescribing. Half of the patients were randomly assigned to once or twice weekly individual psychotherapy with psychiatric social workers (high contact). The brief monthly interview with the psychiatrist comprised the only contact for the other half (low contact). All patients continued to receive amitriptyline for a transitional phase of 2 more months. At this point, after 3 months of treatment, patients were further randomized as to drug. Within each contact group, one-third of the patients continued on amitriptyline, one-third were withdrawn and put on placebo (double-blind), and one-third were withdrawn overtly onto no medication. Treatment then continued in these six treatment cells for a further 6 months (9 months total treatment—4 to 6

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Weissman is Director, Depression Research Unit, Connecticut Mental Health Center, 904 Howard Ave., Suite 2A, New Haven, Conn. 06519, and Associate Professor of Psychiatry (Epidemiology), Department of Psychiatry, Yale University School of Medicine, where Dr. Kasl is Professor of Epidemiology, Department of Epidemiology and Public Health. Dr. Klerman is Professor of Psychiatry, Harvard Medical School, Massachusetts General Hospital, Boston, Mass.

This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grants MH-13738 and 15650 from the Psychopharmacology Research Branch, National Institute of Mental Health.

Alberto DiMascio, Ph.D., Director of Psychopharmacology, Department of Mental Health, Commonwealth of Massachusetts, Boston, Mass., was the principal investigator of the Boston State Hospital Clinic.

weeks in acute treatment and 8 months in maintenance); at the end of this time the controlled treatment ended. All patients were followed 6 months and 1 year after maintenance treatment.

All of the patients in this study were women. Most were in their late 30s, and they were typically from the middle and lower middle social classes (6). According to criteria from *DSM-II* (7), 85% of our patients were diagnosed as having neurotic depressions. The majority of the patients had had only one previous episode of depression. Since only 5% of the patients had had a previous episode of mania, the majority fell within the unipolar group. Therefore, the typical patient was neurotic, depressed, ambulatory, and nonpsychotic and for the most part had had one or no previous episodes of depression.

All patients were still living and were located. Over 90% of the patients at both follow-up periods participated in a face-to-face 2-hour interview, in which a research assistant and a psychiatrist covered the patient's clinical course and treatment experiences over the preceding 6 months. This information was supplemented with a review of the patient's records. The patient's clinical status was assessed by the Raskin Depression Scale (5) and the Clinical Interview for Depression (8), a modification of the Hamilton Rating Scale for Depression. Social functioning was assessed by the Social Adjustment Scale (9).

RESULTS

Clinical Course

There were no completed suicides during the entire study or follow-up. However, 3 patients (2%) attempted suicide during follow-up. These were first attempts for 2 of the 3 patients; all were considered minor, and only 1 led to a brief hospitalization. Fourteen patients (10%) at 6 months and 21 patients (15%) at 1 year had again reached the original symptom criterion for admission for acute treatment (Raskin Depression Scale score of 7 or more) (table 1). However, that 3 patients received a Raskin score of 7 or higher on both occasions is indicative of the fluctuating clinical course of these patients.

In addition to these cross-sectional assessments, a retrospective assessment of the patients' monthly symptom status over the year indicated that minor low-grade symptoms were common. Mild to moderate symptoms returned for 88 patients (59%), 18 patients (12%) remained chronically symptomatic, and only 43 patients (29%) were completely asymptomatic during the year.

Treatment Experiences

Another indication of the patients' clinical course is the amount and type of treatment they received during the 1-year follow-up. Only 45 patients (30%) did not receive any treatment; 37 patients (25%) received treatment for 1–2 months; 30 patients (20%) received treatment for 3–6 months; and 33 patients (22%) received treatment for 7–12 months. Over the entire 1-year follow-up, 7% of the patients never had a month without treatment.

TABLE 1
Clinical Status on the Raskin Three-Area Scale of Depression at 6 Months and 1 Year

Raskin Score (Range 3–15)*	6-Month Follow-Up		1-Year Follow-Up	
	Number	Percent	Number	Percent
3–4 (asymptomatic)	84	59	72	52
5–6 (borderline)	45	31	45	33
7–8 (requiring treatment)	10	7	15	11
9+ (moderate to severe depression)	4	3	6	4

* Higher scores indicate more impairment; 7 or above was the initial criterion for treatment of acute depression.

When we examined the type and intensity of treatment, we found that nearly all treatment had been on an outpatient basis. Only 2 patients had been hospitalized over the year—both briefly—and none had received day hospital care. The intensity of treatment was low, usually one to two visits a month. Psychotropic medications, usually tricyclic antidepressants and minor tranquilizers, were commonly prescribed. Over 50% of the patients were receiving psychotropic medications at the time of each interview.

Sustained Effects of Maintenance Therapy

When we examined sustained effects of amitriptyline versus psychotherapy, no striking differences emerged. We found that patients who had received maintenance amitriptyline took significantly more psychotropic medications (not necessarily tricyclics) during the first 6 months than patients who had received no medication. The patients who had received maintenance psychotherapy also tended to receive more frequent treatment in the first 6-month follow-up. Both of these findings suggested a tendency for patients to initially continue seeking in the follow-up period a treatment that was similar to what they had received in maintenance therapy.

We next examined the clinical status and social adjustment of the patients at the two follow-up periods. We divided patients according to their maintenance treatment and did a three-way analysis of variance with three factors (by maintenance drug and contact and by hospital). The results of these analyses did not show any differential sustained effects of the maintenance treatment. However, there is a problem in interpreting these results since pure treatment groups no longer remained. Treatment was not controlled in the follow-up period, and patients sought a variety of treatments.

It was possible that an interaction between treat-

ments received in the maintenance and follow-up phases might be obscuring the results. For example, patients who received psychotherapy in follow-up but not in maintenance may be less symptomatic than patients who did not receive psychotherapy either time. Similar crossover effects could be postulated for the drug groups. In order to test this possibility we did several two-way analyses of variance, looking at maintenance and follow-up treatment and their interactions, and using the patients' clinical and social adjustment status at follow-up as outcome. The results of these analyses showed no interaction between treatments, but a main effect for treatment received in follow-up indicated that the patients who received the most treatment in follow-up (drugs or psychotherapy) were the most symptomatic at follow-up. A month-by-month analysis of the patients' clinical and treatment status indicated clearly that this association was due to the fact that patients sought and received treatment if they experienced a return of symptoms.

DISCUSSION

Three aspects of these findings merit attention: the absence of a differential effect of the various maintenance therapies once they ended, the variable long-term clinical course of these patients, and the implication of these results for planning care on an individual and a public health basis.

The absence of a sustained effect of the tricyclic antidepressant once regular maintenance treatment ended is consistent with expectations. Antidepressant therapy appears to suppress symptoms while the natural processes of recovery take place. Once treatment ends there may be return of symptoms. Maintenance therapy, therefore, is not prophylactic. It does not appear to have an action on the etiological or pathogenetic determinants of the disorder.

There are many such parallels in medicine, e.g., digitalis for heart disease, aspirin for fever, diuretics for edema, cortisone for inflammation. While none of these drugs, once terminated, is expected to prevent future symptoms of the illness for which they are used, they remain important treatment modalities.

The expectations for psychotherapy are slightly different. In psychotherapy the patient is expected to develop understanding about situations that may have contributed to the depression or developed as a consequence. There are several possibilities for the absence of a sustained effect. Eight months may not have been a sufficient length of time, especially since it took that long for the psychotherapeutic effect to develop. The psychotherapy was of a supportive nature rather than an attempt to reconstruct past experiences, which would have presumably led to more enduring change, and was given by social workers (although experienced and highly trained) rather than by psychiatrists. Patients were initially treated with drugs alone and were clearly drug responders. Further research is needed on the efficacy of different types of psychotherapy in depression, given by psychiatrists and begun earlier in the treatment, to determine if more lasting effects can be achieved.

The rationale for maintenance therapy is based on the fact that many patients are likely to have recurrences after they have recovered. These results show that even after 8 months of maintenance therapy patients' clinical courses were highly variable and the majority experienced intermittent symptoms. The clinical course can best be described in terms of remissions, recurrences, and chronicity.

Remission refers to a sustained absence of symptoms following an acute episode (defined as a discrete period of psychopathology that can be distinguished from prior functioning). Only about 30% of the patients remained in complete remission over the year.

Recurrence is the reemergence of symptoms following a sustained (usually several months) symptom-free interval. The majority of patients (nearly 60%) experienced recurrences. Ten percent of the patients at 6 months and 15% at 1 year were as symptomatic as they had been during the acute period. Moreover, there was little overlap between these two groups at the two time periods. On the basis of the Raskin Depression Scale scores at each follow-up, 32 patients (21%) had had a new, documented episode of depression over the year. The remaining patients reported intermittent mild return of symptoms over the year. These symptoms included pessimism and disturbances of affect, appetite, and sleep, which were easily controlled by medication and brief treatment and rarely required hospitalization.

Chronicity is the presence of continuing symptoms without a sustained symptom-free interval. In addition to the nearly 60% of patients with a recurrent episodic course, there was an important group (12%) who remained chronic over the entire year. The percent of chronically symptomatic patients shows some similarity with other reports. In a 1966 New Haven survey of depressed patients entering a variety of treatment facilities, 10% of the patients remained symptomatic 10 months after the index episode (10). Robins and Guze (11), in a review of 12 studies of depressed patients who were followed for up to 20 years, found that 11%–23% had a chronic course. Murphy and associates (12) did a 5-year follow-up on patients diagnosed as having primary affective disorder and found that 16% were chronically ill during the entire period.

Although the definition of chronicity, the time of observation, and the types of patients vary in these reviews, they suggest that a substantial minority of patients have a chronic course. It is unclear whether this is due to insufficient or incorrect treatment.

Given the variable course of depression and the absence of a sustained effect of treatment, how can these results be translated into the care of individuals? One approach might be to prolong maintenance treatment, but the cost, the potential for side effects with indefinite drug treatment, and the dependency fostered by

indefinite psychotherapy would argue strongly against this notion for all patients. An alternate approach would be to offer care on a continuing basis when needed. In this way early signs of pending relapse could be treated promptly, and regular care would be available to the few patients who need it. Our results show that about 10% of the patients will require regular continuing treatment, perhaps on an intensive basis, 30% will require no treatment for sustained durations, if at all, and the remainder will need episodic care that is not intensive. Further work should be done to identify earlier that subgroup of patients who remain chronic and to determine if longer maintenance therapy or changes in medication improve their clinical course. At present we cannot predict the outcome of the individual case.

The implications of these findings for planners center around the need for flexibility of treatment resources so that patients can have crisis intervention for acute episodes, as well as continuing care as needed. Whatever the intensity of treatment, it should be planned longitudinally to provide continuity and accessibility. In this regard, depression shares many features of nonpsychiatric chronic diseases (13). Current health policy in the United States is focused on chronic diseases with high mortality. Mental disorders that have a high morbidity and potential mortality, such as depression, also require long-range comprehensive planning.

The conventional psychiatric literature has emphasized the tendency for neurotic depressions to be relatively benign (12), to resolve rapidly, and to leave minimal cognitive impairment between episodes. In fact, our results indicate that there are often chronic or intermittent residuals, which impair the personal lives, personal happiness, and family adjustment of such patients.

Current Issues in National Insurance for Mental Health Services

BY SCOTT H. NELSON, M.D., M.P.H.

The current economic crisis has again placed in jeopardy the inclusion of mental health benefits under national health insurance. The author notes that progress has been made in establishing effective peer review systems and in demonstrating that costs of mental health services are reasonable. Yet the lack of agreement on diagnosis and appropriate treatment, the inadequacy of utilization, cost, and treatment outcome data, and the absence of professional self-regulation remain causes for concern in the effort toward eventual comprehensive coverage for mental disorders.

CONSIDERABLE PROGRESS was made vis-à-vis the inclusion of mental health benefits in proposed national health insurance legislation over the 3 years from 1972 to 1974. In 1972 relatively few proposals provided any substantial coverage of mental disorders; in 1974 virtually all the major proposals submitted to Congress contained a significant (although limited) benefit package. Most striking was the change in the proposal put forth in 1974 by the President; it shifted from no coverage at all to a respectable benefit package of 30 inpatient or 60 partial hospitalization days and 15 individual visits to a private practitioner or the cost equivalent of 30 individual visits in an "organized care setting" (OCS). The reasons for the shift are complex but probably have to do with the recognition by lawmakers and social policy officials of the substantial need for coverage of mental disorders, as well as with the pressures that were applied by a variety of constituency groups.

In 1974 there was as much agreement on the benefit package that should be offered under national health insurance as we are likely to see for some time. Arguments came not over the services to be covered, but over such technical aspects as the mechanism of financing (i.e., through private insurance carriers or the federal government) and voluntary versus compulsory enrollment.

In 1976, however, the economic crisis, with its accompanying recession, rising costs and prices (especially in the area of health care), and unemployment, has been the major factor in a changed situation. Economic concern has caused legislators and policy makers to scrutinize expensive proposals such as national health insurance (NHI) with increasing care. As in 1972, the matter of what benefits might be covered under any national health insurance law is again an open question.

In times of economic constraint, mental health benefits are often unfortunately among the first to be considered for exclusion. Recently considerable pressure has been placed on Congress to consider the elimination of mental health, drug abuse, and alcoholism benefits in the Health Maintenance Organization (HMO) legislation; these benefits are already limited to 20 outpatient mental health visits and detoxification services for alcohol and drug addiction. Since they became law in 1965, Medicare and Medicaid have routinely limited the amount of coverage for care of mental disorders, particularly outpatient care.

Yet new evidence has been put forth by Brenner (1) indicating that during economic crises, with their concomitant social and personal stresses, the incidence of mental disorder, drug abuse, and alcoholism rises dramatically, as expressed by increased demand for services for these conditions during such periods.

ARGUMENTS FOR INCLUSION OF MENTAL HEALTH SERVICES

The best known argument of proponents of financial entitlement for mental health services is the logical one of fairness—that adequate services should be financially available to persons with alcohol, drug abuse, or emotional problems just as they are for other health problems. But this position has been explicitly challenged by legislators and policy makers from several points of view. Such individuals contend that there are inadequate criteria for determining when a person has a problem that requires service, i.e., that service is often determined more by patient demand rather than by objective, scientific criteria of need. Opponents of mental health coverage also argue that a definition of "adequate services," either type or amount, is not available for most mental health conditions and that many of the services provided by mental health practitioners cannot legitimately be called "health" services. At least one further difficulty is that much of the care of chronic patients and the poor has been provided by publicly funded institutions that have had

Dr. Nelson is Director, Office of Program Planning and Evaluation, Alcohol, Drug Abuse, and Mental Health Administration, U.S. Department of Health, Education, and Welfare, Parklawn Building, Rm. 12C-26, 5600 Fishers Lane, Rockville, Md. 20852.

little access to other reimbursement systems; because of tradition and bias there appears to be resistance to the idea of changing this system of providing and paying for care.

Given the relative lack of acceptance of adequate coverage that has been encountered in many policy- and law-making areas, proponents of quality care for mental disorders, drug abuse, and alcoholism have recently focused on two more specific arguments for inclusion of benefits for such care under national health insurance. These arguments are based on projections of reasonable cost and plans for improved accountability for services rendered.

COSTS OF MENTAL HEALTH CARE

Recent experience in covering mental health treatment under insurance plans indicates that the cost is not excessive and does not rise at rates that are out of proportion to those of physical illness. Reed and associates (2) reported several studies showing that the utilization of mental health services under insurance plans is low and therefore that the cost of mental health services in comparison with costs for physical conditions is reasonable.

Some of the low percentage costs of mental health coverage under insurance plans can be explained by the restrictive limits on care in some of the plans. However, even in those few plans that provide nondiscriminatory coverage, such as some of the carriers[1] in the Federal Employees Health Benefits Program, the proportion of costs has ranged between 7.5% and 12% (3), probably averaging slightly less than 10%.

Many have pointed out that trend data over the past 4 years indicate that the percentage of total expenditures for mental health care under one of these federal employee plans (the Blue Cross and Blue Shield plan) appears to be plateauing at about 7.5% (4). Some have concluded that since coverage for mental health services is complete under this plan (except for the $100 deductible and 20% copayment by the patient), percentage costs for mental health coverage are unlikely to rise above this 7.5% level.

Unfortunately, the plateau phenomenon seen in the Blue Cross and Blue Shield plan does not tell the whole story. The reason for this is that until recently, as already noted, there was more than one carrier with essentially nondiscriminatory mental health benefits. Federal employees may switch insurance carriers during an open enrollment period once each year; therefore, the plateau phenomenon could be explained either by stable percentages of cost *or* by shifts in the users of psychiatric benefits from one insurance plan to another. In the past year, the Blue Cross and Blue Shield plan has become the *only* carrier to offer the nondiscriminatory mental health benefit. Data from the next 2 or 3 years' experience therefore will be needed before it is known whether or not the plateau is genuine.[2]

Projections of what overall percentage of total health costs might be spent for either limited or unlimited mental health services under national health insurance are difficult to make. This is because utilization patterns differ considerably according to the population covered. For example, the United Auto Workers were found to have a lower utilization of benefits than would have been expected on the basis of an assessment of need and their financial entitlement (5). On analysis, this phenomenon was felt to be based on the perceived stigma of mental health treatment, the lack of knowledge that a psychiatric benefit was included in the insurance plan, and the lack of belief in the effectiveness of mental health care (6).

In contrast, in the Washington, D.C., area there is the highest rate of utilization of mental health services in the nation. This is explained in part by the fact that a large number of mental health professionals, particularly psychiatrists and psychologists, are located in Washington and that psychologists as well as psychiatrists are eligible for reimbursement under the two largest federal employee plans. In addition, federal employees are a well-educated group who work under conditions of considerable stress in the highly political metropolitan Washington environment. Conditions of high stress are known to lead to psychiatric symptoms, and education also correlates strongly with use of mental health services.

If unlimited mental health benefits were included under national health insurance, utilization rates would vary by geographic area but probably would average substantially less than that of the nation's capital.

EFFECTIVENESS OF REVIEW PROCEDURES

The second argument that is commonly used to justify inclusion of mental health benefits under national health insurance is that mechanisms of accountability, particularly in the form of peer review, will be effective. Increasingly concerned with the review of insurance claims for mental disorders, and under increasing pressure from the public and the courts to correct abuses and provide high quality care, the fields of psychiatry and psychology have instituted peer review committees in local professional associations and in some mental health service settings. Psychiatrists have been active participants in the development of standards and in the implementation of the Profes-

[1]In 1975 the Aetna plan cut back its benefit for outpatient treatment of mental and nervous disorders to 20 visits a year (40 if the service is provided by a qualified community mental health center).

[2]Newly available Blue Cross and Blue Shield data indicate a continuation of the plateau in 1975; mental health costs comprised 7.5% of total health costs in 1975 compared to 7.2% in 1974 and 7.3% in 1973. Total mental health costs, however, increased by $20 million (to $90.8 million) in 1975, compared to increases of less than $10 million per year in the previous 4 years. Total health costs also rose sharply in 1975, accounting for the constancy of the percentage of total costs spent for mental health care.

sional Standards Review Organization (PSRO) program (7).

The increased scrutiny of clinical practice resulting from review processes will undoubtedly lead to more attention by mental health professionals to delivering an appropriate quantity and quality of care. However, one of the problems is that the outcomes of psychiatric treatment are not demonstrable in as objective and scientific a way as are the results of the treatment of such conditions as pneumonia and appendicitis by other branches of medicine. Mental health professionals may disagree about the diagnosis for a given patient, and even when there is agreement on diagnosis there may be differences concerning the modality of treatment that should be used. This situation makes the justification of an appropriate type and length of treatment difficult.

Still, it is reasonable to expect that with more stringent review of care mental health professionals will curtail what might be judged by their peers (and even by others) as inappropriate service. In addition, the peer review process will serve the function of continuing education for those practitioners who need it. With more definitive studies on the outcome of various treatment modalities, the process of peer review will be an even more effective vehicle for assuring appropriate and adequate care, and will assist with the objective of cost containment as well.

The Community Mental Health Center of Peninsula General Hospital, located in Burlingame, Calif., has used a peer review system for the past 4 years and has found it to be an effective way of staying within its allocated budget for treatment provided to certain groups of patients (8). Another example of effective peer review is seen in the cooperative working agreement between the National Institute of Mental Health and the Department of Defense in which the care delivered in residential treatment facilities for emotionally disturbed children is being reviewed by 20 interdisciplinary mental health teams. This review process was initiated because of evidence of grossly inadequate inpatient treatment for children whose care was being paid for by the Civilian Health and Medical Program for the Uniformed Services (CHAMPUS) program, which primarily serves military dependents. On the basis of this review, more than half of the claims for reimbursement for care of children hospitalized more than 120 days were disallowed, and CHAMPUS has taken steps to disqualify many of the facilities from reimbursement because of their failure to meet professional standards. While the CHAMPUS situation is probably not representative, it does illustrate the potential utility of the peer review process as a mechanism for both quality of care and cost containment.

COST CONTROL VERSUS NEED AND DEMAND

One of the major concerns of opponents to coverage of mental disorders under national health insurance is that the demand for services may be directly related to an individual's insurance entitlement as well as to the manpower available to provide treatment.[3] Yet a recent survey (9) indicated that the rate of utilization of mental health services by uninsured individuals was no greater than that of persons who were insured. Still, because the mental health field has inadequate criteria to define the need for treatment and frequently does not agree on diagnosis or treatment modality, the task of convincing economists and social policy makers that there is a circumscribed amount of need will be difficult.

Skeptics also point out discrepancies in arguments with regard to need and cost. They point out that on the one hand mental health practitioners are encouraging patients to recognize symptoms and to seek care early in the course of their troubles. If everyone did this, substantial increases in demand for services might be generated and the proportion of costs expended for mental health care eventually could rise to levels that are unacceptable to policy makers. On the other hand, using the argument that utilization is low and therefore cost of coverage is reasonable as an argument for including mental health services contradicts the goal of early and frequent treatment (which may in turn save the subsequent cost of more extensive care). It also does not address the issue of the need for financial support of adequate amounts and quality of care (assuming that a widely acceptable definition of "adequacy" could be developed). Indeed, to invoke the low percentage of total health insurance cost as an argument for including mental health coverage under NHI may create an undesirably low expectation for the cost of mental health service, when estimates and data show that mental health costs are actually about 15% of total health costs, both in this country and abroad (10, 11); this figure includes public mental hospital care.

One strategy being considered for dealing with the desire to both control costs and assure optimum allocation of resources is the establishment of a financial ceiling on the amount available for coverage of mental disorders, allowing local practitioners to divide the "pot" according to which individuals are felt to need treatment most. Many administrative problems would result from attempting to implement such a strategy, but it appears to be a concept that is being considered increasingly by some policy makers.

Another option that has been proposed is to provide financial entitlement only to those persons who have emotional conditions that are based on definitive physical (i.e., medical) causes, such as psychoses and brain syndromes. Treatment for other conditions would have to be financed in some other way. Yet many conditions, even among the psychoses, have no clearly demonstrated physical causes.

A more likely first step in the current economic cli-

[3]It would be useful to study whether this is more the case for mental than for physical conditions.

mate is the passage of catastrophic (rather than comprehensive) legislation, in which health expenses above a specific dollar level would be reimbursed. The best-known proposal, the Long-Ribicoff Bill (S-2470), would also provide for nationalization and improvement of the Medicaid program and modifications to Medicare and would establish certain requirements for insurance companies providing routine coverage. While the catastrophic approach has limitations in that it does not provide the leverage for needed change in the total health system, it does offer some opportunities for improved mental health, drug abuse, and alcoholism coverage in preparation for eventual implementation of a more comprehensive insurance program.

NONPHYSICIAN MENTAL HEALTH PROVIDERS

If the need for mental health services cannot be defined in an objective sense, and if significantly increased demand may be generated with more liberal financial entitlement to service, the number of providers who are eligible to deliver services and obtain reimbursement becomes a significant cost issue. Psychologists are rapidly achieving equity with psychiatrists in the delivery and reimbursement for mental health services, and other mental health professionals such as social workers and nurses are not far behind in their demands for recognition as independent practitioners.

Unfortunately, reimbursement criteria are usually drawn along disciplinary lines rather than by measures of which practitioners have the appropriate training, experience, and competence and thereby merit payment for their services. It has been suggested that criteria are needed by which the competence of trained and experienced clinical practitioners, regardless of discipline, can be judged and through which reimbursement for services delivered can be made (12).

Certification and recertification, with provisions for continuing education, should also be required. It is striking in this regard to note that the field of psychiatry does not require specialty certification of psychiatrists; in addition, there is no required system in any mental health discipline to assure continued proficiency or familiarity with new developments in the field, although at least three states (New Mexico, Maryland, and Oregon) now require some continuing education for relicensure of physicians. Such self-regulation activities as certification, recertification, and continuing education should be paramount concerns for the mental health disciplines, particularly with the increasing public concern with quality care and malpractice.

CONCLUSIONS

With continuing concern on the part of economists and policy makers about the rising costs of health care and the need for improved accountability, the field of mental health finds itself in a particularly vulnerable position. Better and more broadly ranging data from insurance and other financing mechanisms need to be collected and disseminated. In many cases such data will not be available without restructuring of current information-gathering practices. Research that demonstrates the effectiveness of various modalities and patterns of treatment is also vitally needed. One can hope that involvement in maintaining and improving systems of peer review will continue to be supported by all mental health professionals.

Whether or not these efforts will be made depends upon the ability of mental health practitioners to take on new roles and clear responsibilities with regard to the costs of and financing policies related to their patients' care. In addition, the abandonment of parochial disciplinary stances in favor of reimbursement criteria based on standards of competence would go far toward lending credibility to the mental health care system. Indeed, some of the most cherished traditions of treatment may need to be examined and changed in accordance with criteria of improved cost effectiveness. Failing this, the mental health field will doubtless continue to be viewed with suspicion and alarm by legislators and policy makers, and increasing numbers of patients who genuinely need mental health services in the future may go without them.

Agitated Psychotic Depression Associated with Severe Hypomanic Episodes: A Rare Syndrome

BY JONATHAN M. HIMMELHOCH, M.D., PATRICIA COBLE, R.N., DAVID J. KUPFER, M.D., AND JANE INGENITO, R.N., M.S.N.

The authors present detailed clinical and follow-up data on 12 patients with agitated psychotic depressions who developed serious hypomanic or manic episodes. In six patients, each type of affective episode seemed to merge into the others, while in the other patients there was always a clear temporal distinction between each type of episode. The authors suggest that the older ages of their patients may have contributed to the syndrome. They also offer several possible theoretical explanations: the patients 1) had mixed affective states and were trapped in the "switch" state from depression to mania, 2) inherited both unipolar and bipolar diseases, 3) represent a subgroup of bipolar patients, and 4) were schizoaffective.

Things are seldom what they seem,
Skim milk masquerades as cream,
Highlows pass as patent leather,
Jackdaws strut in peacocks' feathers.

—W.S. GILBERT
H.M.S. Pinafore

KRAEPELIN'S EVENTUAL decision to include under the broad concept "manic-depressive insanity" each of the clearly described depressive syndromes he had so carefully differentiated (1, 2) has had confounding effects on succeeding generations of psychiatric theoreticians. Kraepelin's immediate psychiatric descendants accepted his final decision and, ignoring his earlier clinical differentiations, telescoped his various depressive categories into the single concept of "endogenous depression." This compression of variety was facilitated by Kraepelin's even earlier decision to separate acquired from constitutional psychiatric illness (3). By 1929 the dualistic reactive-endogenous concept of depressive disorders had developed (4). This view reigned over psychiatric thinking until the past decade, when it has been challenged by "pluralistic" or categorical conceptualizations, recently discussed by Klein (5). However, recent classification systems are implied in Kraepelin's descriptions if not in his theory.

Nevertheless, for most of this century "endogenous depression" has been synonymous with the "melancholia" of Galen, Burton, Sydenham, and Willis (6)—namely, severe depression characterized by apprehension, agitation, severe sleep disorder, nihilistic and somatic delusions, and delusions of sin. A natural consequence of this thinking has been the identification of melancholia as the depressed phase of manic-depressive illness, as can be seen in the works of Freud (7), Abraham (8), and numerous other investigators up to the present time.

But Kraepelin originally did not believe that melancholia, which he called "apprehensive depression," was the depressed phase of manic-depressive illness (2). He reserved motor retarded, "volitionally inhibited" states for this role. Evidence (9, 10) that bipolar affective disorder is genetically different from unipolar affective disorder has revived interest in this distinction as a means of clinically separating the depressive phases of these two genetic subtypes of primary affective disorder.

Beigel and Murphy (11) have produced evidence which strongly suggests that motor retardation is the identifying clinical characteristic of the depressed phase of bipolar illness. Detre and associates (12) and Kupfer and associates (13) showed with all-night sleep EEGs and telemetric analysis of mobility that individuals with bipolar depression are usually hypersomnic and motor retarded while individuals with unipolar depression are usually hyposomnic and agitated. There is also evidence that biochemical (14, 15), endocrinological (16, 17), perceptual (18, 19), and pharmacological (20, 21) differences separate retarded bipolar depression from agitated unipolar depression (one form of which is classical melancholia).

In reality, agitated psychotic depression is rarely associated with clinically significant hypomania or mania. While patients frequently describe a brief period of mild euphoria when an agitated depression lifts (22), the elation lasts for only a short time before

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are with the Western Psychiatric Institute and Clinic, University of Pittsburgh School of Medicine, 3811 O'Hara St., Pittsburgh, Pa. 15261, where Dr. Himmelhoch is Associate Professor of Psychiatry and Director, Affective Disorders Clinic; Ms. Coble is Research Associate, Sleep Laboratory; Dr. Kupfer is Professor of Psychiatry and Director of Research; and Ms. Ingenito is Associate Program Director, Crisis Evaluation Unit; at the time this work was done, she was Program Director of the Unit.

the patient resumes the mildly anxious and obsessive style that marked his premorbid personality. From 7 years' experience in two major clinics for affective disorders in which we have treated over 800 patients, 550 of whom were clearly manic-depressive, we know of only 12 patients with agitated psychotic depressions who went on to develop hypomanic or manic episodes long enough or severe enough to produce social disruption and merit pharmacological intervention.

It is the purpose of this paper to report detailed clinical and follow-up data about this select group. We believe these data have important theoretical and clinical implications for the understanding of the nature and treatment of affective disorders.

METHOD

Clinical data were obtained using the Kupfer-Detre System (KDS) (23) and thorough clinical interviews. The KDS is a combination of clinician-administered and self-administered questionnaires that is an effective tool for compilation and analysis of detailed neuropsychiatric, medical, family, and sociodemographic data. The history of one patient, who had committed suicide 3 years earlier, was gathered retrospectively from her twin sister. This patient was the only one in the group with any history of sedative, alcohol, psychomotor stimulant, or psychedelic drug abuse. All-night sleep EEGs were performed in 4 patients when they had been drug free for at least two weeks. The sleep records were analyzed according to methods previously described (24).

RESULTS

Demographic, Anamnestic, and Follow-Up Data

Eleven patients were 45 or older, 8 were women, and 6 were Jewish. Of particular interest is the fact that 10 of the subjects (excluding patients 7 and 10) had strong family histories of affective disorders. Patients 8 and 11 clearly had both typical unipolar and typical bipolar family members. Five subjects (patients 1, 2, 3, 5, and 12) seemed to have only bipolar illness in their backgrounds. There was one set of identical twins in the sample (patients 2 and 3) and 1 patient who had an identical twin not included in the study (patient 12); both sets were concordant for this particular affective syndrome.

Five subjects (patients 1, 5, 6, 9, and 11) had been diagnosed by other clinicians as schizo-affective, but careful analysis showed that all of their psychotic and cognitive symptoms were acute, episodic, and affective in nature. Residual, interepisodic symptoms were invariably of an affective type.

Preoccupation with suicide was a prominent feature of these patients' histories. Eight patients (1, 2, 3, 6, 8, 9, 11, and 12) had suffered from suicidal ideation during their acute depressions. Seven of these (excluding patient 12) had made serious suicide attempts, with patient 3 succeeding. The suicide attempts and gestures of 5 patients were remarkable for their violent means (stabbing, slashing, and shooting). Suicide was also a prominent factor in the family histories of these patients.

Finally, these patients seem more difficult to treat than either typical unipolar or typical bipolar patients. Follow-up periods have ranged from 18 to 36 months, and treatment response has been less than optimal in 10 patients. Two subjects (patients 3 and 9) were treatment failures; 1 committed suicide, and the other was chronically institutionalized. Four subjects (patients 1, 6, 8, and 10) had significant symptomatic improvement after treatment with lithium carbonate but never experienced total remission and needed much psychological support, frequent changes in lithium dosage, and occasional adjunctive treatment with tricyclic antidepressants or monoamine oxidase (MAO) inhibitors. Four others (patients 4, 5, 7, and 11) experienced symptomatic remission with lithium carbonate but needed frequent changes of dose. Two of them (patients 7 and 11) needed an MAO inhibitor (tranylcypromine) when their anergic depressive symptoms resumed. Only 2 subjects (patients 2 and 12) experienced complete remission.

Analysis of Most Recent Agitated Episode

The 12 patients are divided into groups 1 and 2 because their agitated depressed episodes evolved in distinctly different ways after they were placed on tricyclic antidepressants.

All 6 patients in group 1 were grossly psychotic (see table 1). Their dysphoria was severe and seemed linked to striking nihilistic and somatic delusional material. (Of the 6 patients in group 2, only 2, patients 8 and 9, showed this degree of disintegration, while another, patient 11, experienced mild somatic delusions.) After administration of tricyclic antidepressants there was a moderately rapid (7–14-day) reduction in the patients' intense dysphoria, accompanied by the appearance of paranoid/irritable symptoms in the place of somatic, nihilistic, or guilt-laden delusions. Over the succeeding 4–10 days the delusions ceased (all subjects except patient 3 received major tranquilizers as needed), and a clear-cut euphoric hypomania developed, which was treated with lithium. With these patients it seemed as if each type of affective episode (retarded depressive, agitated depressive, manic, and hypomanic) merged into the others.

On the other hand, 4 subjects in group 2 (patients 7, 8, 9, and 11) failed to show any response to tricyclic antidepressants (see table 2). The 2 subjects (patients 10 and 12) who did become hypomanic while receiving amitriptyline never experienced a paranoid/irritable phase. With the patients in group 2, there was always a clear temporal distinction between each type of affective episode.

TABLE 1
Analysis of Most Recent Agitated Episode for Patients in Group 1

Patient	Age	Clinical Features	Acute Course and Response to Medication	Suicidal Ideation/Attempts During Episode	EEG Sleep Data
1	59	Early morning awakening, severe hyposomnia, agitation, somatic delusions (his body was rotten, and his heart had turned to stone). Gave no history of manic episodes at time of acute episode, only after he had become hypomanic.	Treatment was started with 200 mg of doxepin (Sinequan) and haloperidol (Haldol) as needed. After 10 days he became agitated and increasingly paranoid and irritable. Somatic delusions ceased. In 4 more days irritability was replaced by clear-cut euphoric hypomania requiring treatment with lithium.	Brought in a gun with bullets. Had also thought of slashing his wrists.	—
2	54	Severe agitation, hyposomnia, early morning awakening, nihilistic and somatic delusions (she was a skeleton and was deteriorating and putrid).	Treatment was started with 200 mg of amitriptyline (Elavil) and thioridazine (Mellaril) as needed. Delusions became grandiose after 8 days; after 3 more days the delusions ceased and the patient became clearly hypomanic, requiring treatment with lithium.	No suicide attempt during this episode. Had taken a massive drug overdose during a previous episode and nearly died.	—
3	50	Twin sister of patient 2. Severe agitation, hyposomnia, and delusional depression complicated by addiction to sedatives, which ended in suicide.	No real trial with any antidepressant medications.	Committed suicide.	—
4	63	Early morning awakening, marked disturbance in sleep continuity, agitation, compulsive pacing, auditory hallucinations (accusatory voices), and somatic delusions of death and deterioration.	Treatment was started with 200 mg of amitriptyline and perphenazine (Trilafon) as needed. After 10 days became increasingly agitated; quality of delusions became grandiose. After 10 more days became nondelusional but was clearly hypomanic and required lithium therapy.	No suicidal ideation or attempts.	Short REM latency, no delta sleep.
5	54	Early morning awakening, disturbance in sleep continuity, 15-pound weight loss, severe agitation and hyposomnia; somatic symptoms led to nihilistic delusions.	Treatment was started with 200 mg of amitriptyline and thioridazine as needed. After 10 days became more agitated and irritable, with systematized ideas of reference, then grandiose delusions. After 10 more days delusions and paranoid ideation ceased, but severe hypomania necessitated treatment with lithium.	No suicidal ideation or attempts.	Short REM latency, no delta sleep.
6	48	Depressed with many somatic complaints. Severe hyposomnia, agitation, early morning awakening, disturbance in sleep continuity, weight loss, delusions of guilt, God, and the Devil, somatic delusions, and auditory hallucinations (accusatory voices).	Treatment was started with 150 mg of amitriptyline and trifluoperazine (Stelazine) as needed. After 7 days became giddy; religious delusions became grandiose, with much bizarre sexual material; became markedly hyperalert, labile, irritable. After 7 more days delusions and dysphoria ceased. Was obviously hypomanic and euphoric on first outpatient visit and required lithium therapy.	Attempted to stab herself when religious delusions were accompanied by accusatory hallucinations.	Short REM latency, no delta sleep.

TABLE 2
Analysis of Most Recent Agitated Episode for Patients in Group 2

Patient	Age	Clinical Features	Acute Course and Response to Medication	Suicidal Ideation/Attempts During Episode	EEG Sleep Data
7	46	Disturbance in sleep continuity, early morning awakening, agitation, hyposomnia, self-deprecation. No psychotic features.	No response to 4 weeks of treatment with tricyclic antidepressants. Depression gradually lifted coincident with lithium therapy but may have run its course anyway.	None.	—
8	64	Depressed 4 years earlier, with severe agitation, early morning awakening, disturbance in sleep continuity, hyposomnia, somatic symptoms, delusions of sin.	Confusional state in response to treatment with imipramine (Tofranil) and amitriptyline; poor response to ECT and isocarboxazid (Marplan). Discharged with only moderate improvement after 7 months. Showed marked improvement when lithium therapy was started 4 years later.	Cut her throat while in the hospital.	—
9	32	Intensely hyposomnic, early morning awakening, disturbance in sleep continuity, severe agitation, somatic and nihilistic delusions, delusions of sin, auditory hallucinations.	No response to 3 weeks of treatment with amitriptyline and thioridazine. Transferred from surgical unit to a psychiatric hospital. Treated with lithium and tranylcypromine (Parnate) because of history of anergic depression and hypomanic episode; seemed to improve.	Severed the flexor retinaculum of her hand and underlying nerves and tendons in a suicide attempt.	—
10	52	Early morning awakening, disturbance in sleep continuity, anxious, agitated, hyposomnic, weight loss. No psychotic features.	No marked improvement with tricyclic therapy; gradually (8–9 weeks) became hypomanic. Improved somewhat with lithium therapy.	None.	—
11	45	Agitated, hyposomnic, disturbance in sleep continuity, early morning awakening. Somatic delusion that she had syphilis, as her father had; delusions of guilt.	No response in the past to treatment with tricyclics and chlorpromazine (Thorazine). Delusions and agitation decreased with lithium therapy. Rapid remission of symptoms when tranylcypromine therapy was started after suicide attempt in the hospital.	Cut her wrist in the hospital and required stitches. Previously had taken a drug overdose.	—
12	59	Severe depression with suicidal ideation, early morning awakening, disturbance in sleep continuity, hyposomnia, agitation, somatic concerns, 6- to 8-pound weight loss. No psychotic features.	Treatment with 200 mg of amitriptyline was started; gradually improved over the next 2 weeks, then became markedly hypomanic. Lithium therapy was started; complete stabilization of symptoms.	Constant suicidal ideation.	Short REM latency, no delta sleep.

EEG Sleep Data

We were able to study the sleep of 4 patients, 3 from group 1 (patients 4, 5, and 6), and 1 from group 2 (patient 12). All 4 showed typical unipolar sleep characteristics (see tables 1 and 2). All-night sleep data for these 4 patients were also compared with those of 1) a group of nonpsychotic unipolar depressives, and 2) a group of psychotic unipolar depressives. There were no significant differences on any measures.

DISCUSSION

General Considerations

The most important fact about this subgroup of patients is the rarity of their syndrome. A small number of bipolar patients do suffer mild-to-moderate agitation and hyposomnia during their depressive phase, but in our experience (25) such patients are almost invariably abusing alcohol, central nervous system sedatives, or minor tranquilizers, and their agitated state never progresses to the development of full-blown somatic and/or nihilistic delusions. Careful anamnestic investigation usually demonstrates the anergic hypersomnic nature of earlier depressive episodes not contaminated by sedative medications. Moreover, all-night sleep EEGs show measurements typical of sedative abuse and/or withdrawal instead of unipolar depressive illness (24).

Only 1 patient described here had ever abused drugs, and she was included in the sample because she was the identical twin of patient 2 and probably suffered from identical depressive episodes before she committed suicide. Three patients had significant medical problems, but while these illnesses may have contributed to the content of their somatic and nihilistic delusions, medical illness could not be invoked as the cause of their affective disorders or as an explanation for the quality of their behavior.

There is no other external factor except age to which the presence of agitated and psychotic features could be attributed. Eleven patients were 45 or older; 8 were 50 or older. Previous factor analytic studies (e.g., 26) have consistently demonstrated that the older the patient, the more likely that his affective syndrome will be of severe or psychotic proportions. It could be postulated that our patients are a group of bipolars in whom advancing age, for one reason or another, has had particularly devastating effects. However, in our experience the catastrophically disorganizing effects of age on the course and prognosis of affective disorders have been almost exclusively limited to unipolar patients. Most bipolar depressive patients remain anergic and nonpsychotic regardless of their age. In these cases we hypothesize that aging either 1) emphasizes the dysphoric core of mania to such a degree that it resembles a psychotic depression or 2) alters and erodes the patient's defensive structure to such a degree that it allows the unipolar part of his heredity to show through. Aging probably also plays a role in these patients' poor response to pharmacological intervention.

Theoretical Considerations

Clinical differences between the patients in groups 1 and 2 give rise to a number of possible theoretical explanations for the source of this rare syndrome, particularly if these possibilities are examined in the framework of the genetic, clinical, and psychophysiological separation of bipolar from unipolar affective disorder.

The Possibility of Mixed States

These syndromes might be conceptualized in terms of the original Kraepelinian description of mixed affective states (1, 2), which are characterized by simultaneous manic and depressive features and are usually experienced by the subject as intensely dysphoric. Court (27) and Bunney and associates (28–30) have used these states as evidence for developing the continuum hypothesis of manic-depressive illness. This theory states that depression and mania are not polar opposite states, but are closely related entities that are probably only quantitatively different. Depression represents mild to moderate illness and mania, severe illness. Mania is viewed as a state with a depressive core, a concept that is clinically supported by the manic patient's tendency to suddenly become sad and tearful in the midst of his excitement, irritability, and grandiosity. Mixed states represent transitional periods as depression switches to mania (the "switch process"), where a patient becomes trapped in the "switch" state. The result is a severely dysphoric and potentially psychotic state. Bunney and associates (28–30) have reported that urinary norepinephrine and cyclic adenosine monophosphate (CAMP) levels are markedly elevated during this "switch" period. They have also noted a simultaneous decrease in overall sleep and rapid eye movement (REM) sleep. Hullin and associates (31) have disputed Bunney and associates' findings of elevated CAMP levels.

Patients in group 1 could easily be seen as "trapped in the switch process." They were all initially dysphoric and psychotic. Under treatment with tricyclic antidepressants, the quality of their delusional material changed from depressive and nihilistic to paranoid/irritable. This sequence of events could be envisioned as the "switch." Unfortunately, we have none of the biochemical data elaborated by Bunney and associates to support this assumption; nor can we lend support to either Bunney and associates or Hullin and associates regarding urinary CAMP concentrations during the "switch" phase. Our 24-hour sleep EEGs do support Bunney and associates' (28–30) original findings.

After the "switch," these patients remained psychotically manic for only a short time before the intensity of their mania diminished to hypomanic levels. It is possible that the tricyclic antidepressants modified the dysphoric core of their manic episodes without altering any of the other qualities that define the manic process. The idea that tricyclics have ameliorating effects on mania has been held by a number of investigators (32).

The Possibility of Mixed Heredities

A second way of viewing these patients is that they might have inherited both unipolar and bipolar diatheses. Given the existence of two separate gene pools, it is logical to assume that such mixed illnesses exist. There were only 2 patients in our study who clearly had both heredities. Both of these patients were in

group 2, and patients in group 2 might be more easily conceptualized in this light. The fact that each patient had experienced both retarded and agitated depressions and that each affective episode was clearly separate from the other makes it seem possible that these patients were suffering from two separate illnesses occurring at different times.

The Possibility of a Separate Subtype of Affective Disorder

There are no compelling reasons to assume that either the unipolar or the bipolar depressive population is homogeneous. There have been a number of attempts to tease out subgroups from each of these populations. Winokur and associates (33) have suggested that the unipolar group can be further broken down into "young onset-female" versus "old onset-male" according to family history. Kupfer and associates (34) have described a subgroup of unipolar hypersomnic retarded depressive patients. Of more interest is a subgroup of bipolar patients labeled by Dunner and associates (17) as "bipolar II":

> In some respects, such as family history, the . . . bipolar II group . . . would seem to be closely related to the bipolar group, perhaps representing individuals with a less severe form of affective illness, reflected in hypomania rather than mania. On the other hand it is our clinical impression that the hypomania . . . is qualitatively as well as quantitatively different from mania. For example euphoria, generally characteristic of hypomania is not universally present in "full-blown" mania. Mania, in fact, may be better described as . . . [dysphoria]. In addition psychotic symptoms are often seen during mania but not during hypomania. Also in our follow-up study we have noted that the . . . "bipolar II" group accounted for a disproportionate number of the patients who committed suicide after discharge from the unit. (p. 363)

There are striking similarities between Dunner and associates' group and our 12 patients, particularly those in group 1. One can postulate, as we have for our patients, that their patients' higher suicide rate may well be secondary to a severe dysphoric and psychotic process that is experienced by the patient in a nihilistic rather than in a grandiose or paranoid way. The relationship between this process and hypomania may be the same as the relationship between mania and hypomania because this state and mania *are* the same process but are experienced and manifested differently.

The Possibility of a Schizo-Affective Disorder

In a study of 420 monozygotic twins concordant for schizo-affective disorder, Cohen and associates (35) pointed out the high incidence of manic-depressive illness in their patients' family trees and also demonstrated an extremely high suicide rate for their patient population. In an attempt to develop more precise criteria for the diagnosis of schizo-affective disorder, Croughan and associates (36) defined the following two groups of patients: 1) 94 patients with predominantly thinking disorders and two few affective features to meet the criteria for a diagnosis of depression or mania, and 2) 110 patients with "two or more qualitatively different thought or behavior disorders in addition to affective symptoms sufficient to meet criteria for [the diagnosis of] depression or mania" (p. 634). This second group also exhibited a significantly higher occurrence of delusions of sin and tended to have a chronic course of illness that was predominantly affective in nature.

It is obvious that many of our 12 patients, particularly those 5 who had been diagnosed at one time or another as schizo-affective, could be viewed in much the same way as either Cohen and associates' twins (35) or Croughan and associates' second subgroup of schizo-affective patients (36). We do not feel, however, that any of our 12 patients were schizo-affective, since their syndromes could be described entirely according to criteria for pure affective disorder. It is probable that the diagnosis of schizo-affective disorder contains a number of poorly understood subtypes of primary affective disorder. But whatever the case, there seems to be little doubt that patients such as ours are more labile, impulsive, suicidal, needy, and difficult to treat than are patients with more typical affective syndromes.

Immunoglobulin Levels in Psychiatric Patients

BY MEIR STRAHILEVITZ, M.D., JULIAN B. FLEISCHMAN, PH.D., GREGORY W. FISCHER, M.D., RICHARD HARRIS, AND NEDATHUR NARASIMHACHARI, PH.D.

In a study of 19 schizophrenic patients, 7 nonschizophrenic patients, and 31 controls, the authors found significantly higher mean serum levels of 1) immunoglobulin A in schizophrenic women than in control women and in schizophrenic blacks than in either schizophrenic whites or black controls, 2) immunoglobulin D in schizophrenic blacks than in schizophrenic whites, 3) immunoglobulin M in controls than in nonschizophrenic patients, and 4) immunoglobulin G (IgG) in schizophrenics whose urine was positive for phenothiazines than in schizophrenics whose urine was negative for phenothiazines. High serum levels of IgG were associated with no or mild hallucinations and low levels with moderate or severe hallucinations. Black female patients had significantly more severe hallucinations than white female patients. The authors discuss the possible implications of these findings.

THE STUDIES ON serum immunoglobulins in psychiatric patients that have been published to date have not, to our knowledge, included evaluations of serum immunoglobulin D levels. They also have not included a detailed evaluation of the relationship between various behavioral variables and serum levels of immunoglobulins.

In the present study, we determined the serum levels of immunoglobulins G, A, M, and D (IgG, IgA, IgM, and IgD) in psychiatric patients and healthy controls, as well as in various diagnostic groups of patients. We evaluated the relationship between the serum levels of the various immunoglobulins and the severity of thought disorder, hallucinations, delusions, and affect disturbance in the psychiatric patients.

Solomon and associates (1) reported a significant elevation in mean IgM and IgA levels in the serum of psychiatric patients as compared to "healthy" controls. However, they found no significant difference in mean serum IgM and IgA levels of schizophrenic and nonschizophrenic psychiatric patients.

Amkraut and associates (2) found that schizophrenics with a high serum IgA level had a poor prognosis.

Strahilevitz and Davis (3) determined the levels of IgG, IgM, and IgA in the serum of schizophrenic patients, nonschizophrenic psychiatric patients and healthy controls, in samples taken within 24 hours of hospital admission. They found a significantly higher level of IgA in schizophrenics compared with healthy controls and nonschizophrenic psychiatric patients. There were no significant differences in levels of IgG or IgM between the schizophrenic group and the other two groups.

Hendrie and associates (4) also studied immunoglobulin levels in psychiatric patients and found that severe disorganizing levels of anxiety were correlated with increased serum IgA levels; in this study, the difference in serum IgA levels between the schizophrenic and the nonschizophrenic groups was not significant.

In another study, Hendrie and associates (5) determined the level of immunoglobulins in patients in an early phase of polyarthritis, and correlated immunoglobulin levels with the presence of the rheumatoid factor. The main finding was that patients with high levels of IgA and to a lesser extent IgM had a higher score on the Holmes social readjustment scale (which quantifies stressful life events) before the onset of polyarthritic symptoms. Bock and associates (6) found low serum IgM level in schizophrenics and low serum IgA level in a group of patients diagnosed as "borderline psychotic" compared to healthy controls.

METHOD

Evaluation of Patients

The patients were seen in the emergency room of the Malcolm Bliss Mental Health Center in St. Louis. Based on the behavior of the patients during the time of the psychiatric evaluation, all patients but one were rated on a 4-point scale (7) on the following 7 behavior-

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

At the time this work was done, Dr. Strahilevitz was Clinical Director of Training and Research, Malcolm Bliss Mental Health Center, and Assistant Professor of Psychiatry, Washington University School of Medicine, St. Louis, Mo., where Dr. Fleischman is Assistant Professor of Microbiology (Immunology), Dr. Fischer was a resident in psychiatry, and Mr. Harris is Research Assistant, Department of Microbiology (Immunology). Dr. Strahilevitz is currently Associate Professor of Psychiatry, Southern Illinois University School of Medicine, 801 North Rutledge St., Springfield, Ill. 62708. Dr. Fischer is now in private practice in New York, N.Y. Dr. Narasimhachari was formerly Research Scientist and Head of the Biochemistry Laboratory, Thudichum Brain Research Laboratory, Galesburg State Research Hospital, Galesburg, Ill.; he is now Research Scientist, Illinois State Psychiatric Institute, Chicago, Ill.

This is an abbreviated version of the paper presented; the original paper is available on request from Dr. Strahilevitz.

al variables: thinking disorder, disturbance in affect, delusions, hallucinations, social withdrawal, autism, and sum symptom score.

For each immunoglobulin, all patients were identified as having a high immunoglobulin serum level (above the median) or low immunoglobulin level (at or below the median). Similarly, each patient was rated on four behavioral variables (thought process disorder, delusions, hallucinations, and affect disturbance) as having no or mild disturbance (rated 0 or 1) or having moderate or severe disturbance (rated 2 or 3).

Information on drugs taken during the last two weeks before admission and information on medical illness were obtained from the relatives and the patient. A blood sample of 30 ml was taken from the patients by venous puncture immediately following the psychiatric evaluation, and a urine sample was also obtained from most of them within several hours after the completion of the evaluation. The blood was kept in a refrigerator at 4° C. until it clotted. The serum was then separated and stored in deep freeze at −17° C. Control serum samples were taken from hospital employees or blood bank donors. All serum samples were coded and were blindly tested for level of immunoglobulins. Urine samples were tested for the presence of phenothiazines by the Forrest universal test for phenothiazines (7).

Criteria For Diagnosis

The final diagnosis was made by the consensus of two psychiatrists who had no knowledge of serum immunoglobulin levels. Schizophrenia was diagnosed according to the criteria of Feighner and associates (8). Patients diagnosed as schizophrenic were further classified as acute, chronic, or chronic with acute exacerbation. The type of schizophrenic illness was defined according to *DSM-II* (9).

Description of Subjects

Schizophrenic patients. Nineteen of the patients included in the study were diagnosed as schizophrenic. Schizo-affective patients were considered a separate diagnostic group and were not included in the schizophrenic group. The urine test for phenothiazines was negative in 14 of the schizophrenic patients, positive in 3 and showed only a trace in 1. The urine of 1 patient was not tested. This group consisted of 10 women and 9 men and 11 blacks and 8 whites. The mean age of the schizophrenic group was 34±11.47 years.

Schizo-affective and nonschizophrenic patients. Of these 11 patients, 4 were diagnosed as schizo-affective and 7 received other diagnoses. Three had a diagnosis of primary affective disorder; 1, senile dementia; 1, possible senile dementia; 1, alcoholism; and 1, acute brain syndrome with mental retardation. The phenothiazine test of the urine was positive in 1 schizo-affective patient and negative in the other 10 patients. This group consisted of 5 women and 6 men and 8 blacks and 3 whites. The mean age of the schizo-affective and nonschizophrenic patients was 44.5±18 years.

Control subjects. Thirty-one hospital employees and blood bank donors were used as "healthy" controls. We had no medical or psychiatric information on these subjects. The group consisted of 16 women and 15 men and 14 blacks and 17 whites. The mean age of the control group was 30.8±11.10 years.

Determination of Indolethylamine-N-Methyltransferase

Serum enzyme levels were determined in all patients but one, and in 11 of the control subjects. The method used for the determination of serum indolethylamine-N-methyltransferase utilized thin-layer chromatography, gas liquid chromatography, and mass spectrometry. The procedure was described in a recent paper (10).

Statistical Analysis

Mean immunoglobulin levels in the various groups were compared by two-tailed Student's t test. Serum indolethylamine-N-methyltransferase levels were correlated with serum levels of the various immunoglobulins by computing the linear regression coefficient. The sum symptom score was also correlated with the serum level of the various immunoglobulins by computing the linear regression coefficient. The serum level of each of the immunoglobulins was correlated with age in the various control and patient groups. Black male patients were compared to white male patients and black female patients to white female patients for their ratings on each of the seven behavioral variables by two-tailed Mann-Whitney U test corrected for ties.

Determination of Serum Immunoglobulins

IgG, IgA, IgM, and IgD were determined independently for each serum by radial immunodiffusion in agar gels (11).

RESULTS AND DISCUSSION

The significant differences between patient groups in mean serum levels of immunoglobulin are presented in table 1 and figure 1.

We found higher mean serum levels of IgA in schizophrenic women than in healthy control women ($p<.05$) and in schizophrenic blacks than in control blacks ($p<.005$). Mean serum IgA levels were also higher in schizophrenic black women than in control black women ($p<.05$) but not in schizophrenic black men as compared with control black men or in schizophrenic white women as compared with control white women. Mean serum IgA levels were higher in schizophrenic blacks than in schizophrenic whites ($p<.025$). The overall data on mean serum IgA levels seem to suggest that both sex (female) and race (black) contribute to the observed difference in mean serum IgA levels between schizophrenic individuals and healthy controls. Even though our observed differences in means are sta-

TABLE 1
Significant Differences Between Groups in Mean Serum Levels of Immunoglobulins

Immunoglobulin	Groups Compared	N*	Serum Level** Mean ± SD		Significance
IgA	Schizophrenic women	10	3.52	0.95	$p<.05$
	Control women	16	2.50	1.16	
IgA	Schizophrenic blacks	11	3.54	1.15	$p<.005$
	Control blacks	14	2.23	0.76	
IgA	Schizophrenic whites	8	2.35	0.85	$p<.025$
	Schizophrenic blacks	11	3.54	1.15	
IgA	Schizophrenic black women	6	3.78	0.80	$p<.05$
	Control black women	7	2.36	1.02	
IgM	Nonschizophrenic patients	7	0.61	0.29	$p<.05$
	Control subjects	31	1.19	0.70	
IgM	Control blacks	14	1.59	0.70	$p<.01$
	Control whites	17	0.86	0.51	
IgM	Control black women	7	1.94	0.80	$p<.02$
	Control white women	9	0.87	0.41

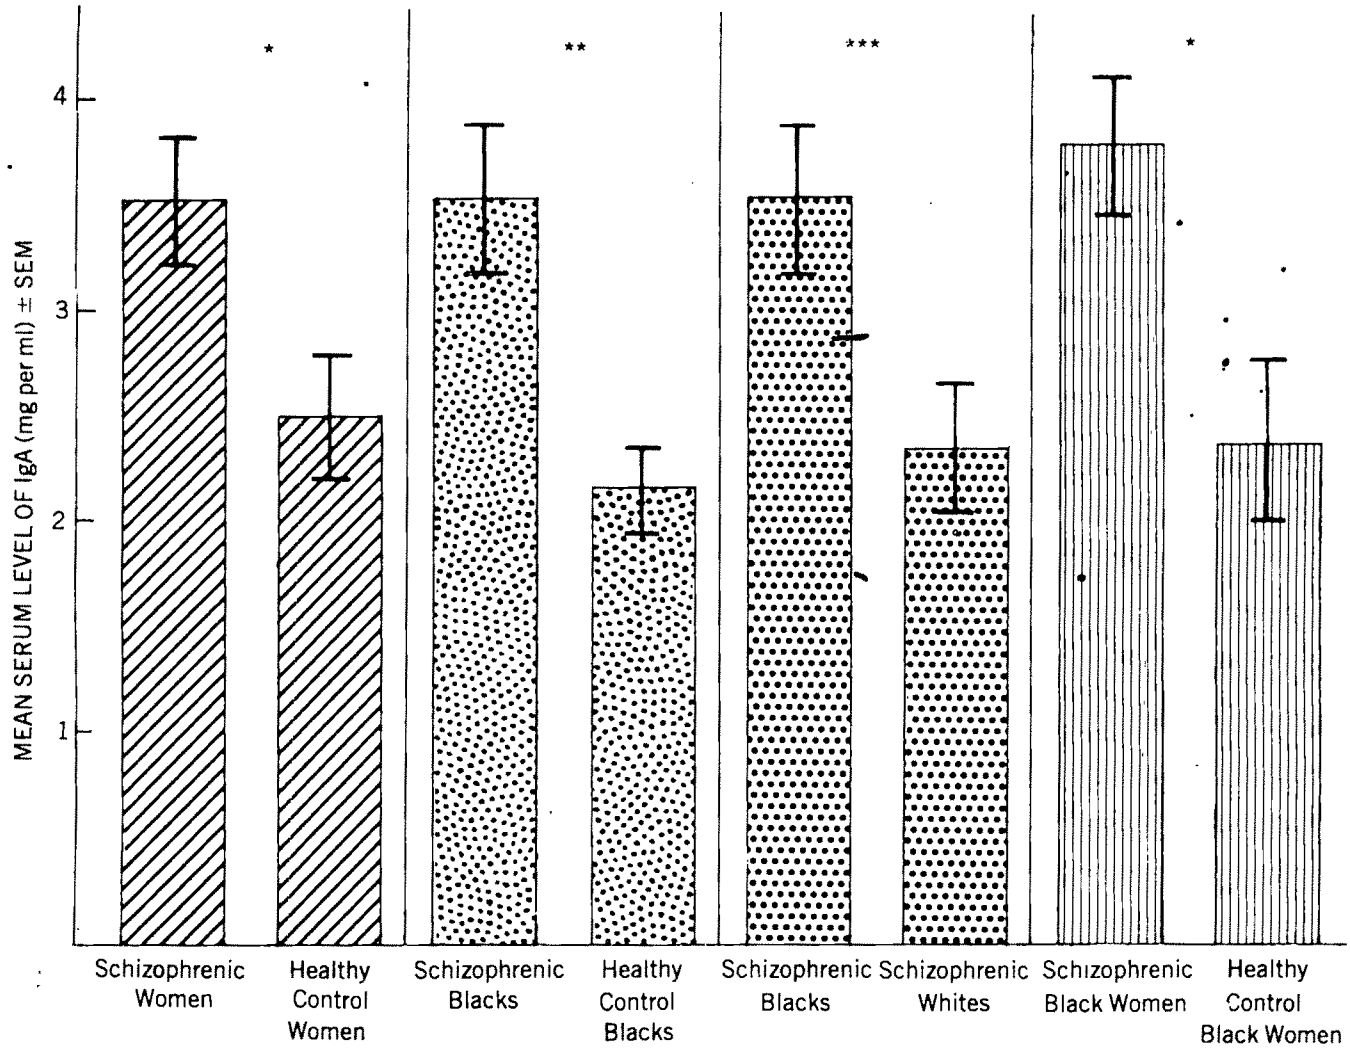
	Schizophrenic blacks	10	59.82	33.33	
IgG	Schizophrenic patients with phenothiazines in urine	4	18.06	3.62	$p<.05$
	Schizophrenic patients with no phenothiazines in urine	14	11.13	5.29	

* Data were not available for some subjects.
** Mean levels of IgA, IgM, and IgG are expressed in milligrams of immunoglobulin per milliliter of serum and mean levels of IgD in international units of IgD per milliliter of serum.

tistically significant, we feel that because of the relatively small size of our samples, and in particular the small size of the sex-race subgroups, our observations should be accepted with reservation until they can be replicated in larger samples and in a number of patient and control populations.

One possibility is that the differences in mean serum IgA levels between black and white schizophrenics could be explained by sex composition of the groups. However, this possibility is unlikely since Buckley and Dorsey (12) found that in adults there was no difference in mean serum IgA levels between men and women or between blacks and whites. In our own healthy controls, mean serum IgA levels were not significantly different between men and women or between whites and blacks.

In addition, the difference in mean serum IgA levels between schizophrenic blacks and control blacks could hardly be explained by a difference in sex composition since there was no significant difference in mean serum IgA levels between control black men and women.



We do not feel that differences in age composition of the various groups could explain the difference among groups in mean serum IgA levels since we did not find any significant correlation between serum IgA levels and age in any of our patient and control groups. Buckley and Dorsey (12) found that changes with age in serum IgA levels in adults are small and not significant.

The observed findings on serum IgA levels are only partly in agreement with the findings of Strahilevitz and Davis (3), who reported significantly higher mean serum IgA levels in schizophrenic patients than in healthy controls or nonschizophrenic patients ($p<.05$, two-tailed Student's t test). These researchers also found that schizophrenic women had significantly higher mean serum IgA levels than control women or nonschizophrenic female patients ($p<.02$ and $p<.05$, respectively). The differences in mean serum IgA levels between schizophrenic men and control men or nonschizophrenic male patients, respectively, were not significant (13).

We found that both mean serum IgA and IgD levels were significantly higher in schizophrenic blacks than in schizophrenic whites ($p<.025$ and $p<.05$, respectively). There were no significant differences in mean serum IgA or IgD levels between black and white control subjects. These observations may be explained by differences in constitutional factors and/or environmental factors between black and white schizophrenics.

Similarly, the significantly higher mean serum IgA levels in schizophrenic women than in control women, in schizophrenic blacks than in control blacks, and in schizophrenic black women than in control black women may be related to both environmental and constitutional or genetic factors. The fact that there were no significant differences in mean serum IgM and IgG lev-

*p<.05.
**p<.005.
***p<.025.

els between black and white schizophrenics suggests that the differences in mean serum IgA and IgD levels cannot be attributed to nonspecific factors such as dehydration and hemoconcentration.

The finding of significantly higher mean serum IgA levels in schizophrenic black women compared with control black women, but not in schizophrenic white women compared with control white women, may be related to the observation that black female patients had a higher rating on severity of hallucinations than white female patients.

Similarly, the higher mean serum IgD in schizophrenic blacks than in schizophrenic whites may be related to either the more severe hallucinations in black female patients, the more severe thought disorder in black male patients, or to both factors.

The increased IgA levels in schizophrenic women, compared with control women, suggest the following two hypotheses: 1) that the increased serum IgA is due to stress, secondary to the illness or concomitantly present at the time of the acute schizophrenic relapse, without being etiologically related to it, or 2) that the increased serum IgA may be etiologically related to schizophrenia. Regarding the possibility that the increased serum IgA may be etiologically related to schizophrenia, the following speculations may be considered. It may be related to the abnormal lymphocytes described in the peripheral blood of schizophrenic adults (14, 15) and schizophrenic children (16) and in the bone marrow of schizophrenic adults (17).

An elevated serum IgA level may reflect an autoimmune process in which antibodies are produced against

a specific brain site, as suggested by Heath and Krupp (18). The antibody described by these researchers is apparently an IgG antibody. It is possible that an IgA autoantibody may also be involved. It should be stressed, however, that the findings of Heath and Krupp could not be confirmed by other researchers, for example Whittingham and associates (19).

Immunoglobulin A is present in relatively large amounts in certain external secretions. At least as far as the parotid gland is concerned, there is evidence that the secretory IgA is locally produced in the gland epithelium (20). It is not entirely impossible that the elevated serum IgA in schizophrenics may be partly produced in the central nervous system (CNS). There is evidence that IgG antibodies are produced in the CNS in subacute sclerosing parencephalitis and in multiple sclerosis (21,22). A secretory IgA antibody was found in the gastric juice of a patient with pernicious anemia. This antibody has been shown to be specific against the gastric intrinsic factor (23). The possibility of local production of IgA antibodies in the CNS with specificity to certain CNS antigenic components is highly speculative but deserves consideration.

The findings of Bock and associates (6) that serum IgA was significantly decreased in "borderline psychotics" is interesting since it may suggest that in relatively compensated psychotics serum IgA may be lower than normal. Unfortunately, these authors did not describe their diagnostic criteria for "borderline psychosis."

We did not find any significant correlation between the serum level of any of the immunoglobulins and the serum level of indolethylamine-N-methyltransferase in any of the groups.

The sum symptom score of behavioral abnormality did not correlate with the serum level of any of the immunoglobulins in either the schizophrenic patients' group or the nonschizophrenic patients' group. Mean serum levels of IgG were significantly higher in schizophrenics whose urine contained phenothiazines, compared with those whose urine did not contain phenothiazines; in addition, in the combined patient sample (N=29), high serum levels of IgG (above median level) were associated with "no hallucinations" or "mild hallucinations" and low serum levels of IgG (at or below median level) with "moderate" or "severe and persistent" hallucinations.

There are two possible explanations for these findings: 1) both observations are due to phenothiazine treatment, i.e., phenothiazines reduce hallucinations and increase serum levels of IgG, or 2) high serum levels of IgG, either drug induced or not drug induced, are etiologically associated with reduction in hallucinations. One speculation is that an IgG antibody may act as a "protective" antibody against hallucinations in psychiatric patients and that both psychotogenic antibodies (IgA?) and protective antibodies (IgG?) may play an etiological role in certain schizophrenic patients similar to the role played by "protective" and "toxic" antibodies in the pathogenesis of experimental allergic encephalomyelitis (24, 25). We feel, however, that both findings should be replicated in another sample before they are accepted as valid.

The observation that nonschizophrenic patients had significantly lower mean serum levels of IgM than controls and that control blacks had significantly higher levels of IgM than control whites can be explained by age and ethnic factors (12, 26).

Prompt Publication Policy

The *Journal* would like to remind authors who are particularly interested in early publication (whether to establish priority of an idea, reveal innovative results of new research, or for other pressing reasons) of its prompt publication policy. Under this policy, short (maximum of six double-spaced pages) manuscripts will be considered for publication in the Brief Communications section of the first available issue. These manuscripts must still undergo expert scrutiny before being accepted, and two months must be allowed for the printing process. However, the time required for publication of these short articles can be lessened considerably.

Authors who would like to have their manuscripts considered under this policy should indicate this desire, as well as the reasons for it, when they submit their manuscripts.

Do Dreams Have Meaning? An Empirical Inquiry

BY MILTON KRAMER, M.D., ROBERT HLASNY, M.A., GERARD JACOBS, AND THOMAS ROTH, PH.D.

Three judges attempted to sort randomly selected dreams of normal college students and schizophrenic patients according to dreamer, night of occurrence, and sequential order within a night. Sorting was successful at statistically significant levels (which differed for the two groups) for all but the third task. The authors conclude that dreams are, as depth psychologists have assumed, orderly nonrandom events and that they reflect day-to-day changes in the life of an individual. They note that further work is needed to determine whether there is order among dreams of a given night.

THE MAJOR depth psychologists of this century have all attributed great significance to dreams (1). Freud hypothesized that dreaming was a disguised attempt to fulfill an infantile, generally sexual, wish. If the attempt was successful, the sleeping state of the person would be preserved. Adler assumed that dreaming was a method of generating appropriate affect in order to rehearse for the activities of the subsequent day. Jung postulated that dreaming had a regulatory function that attempted to compensate for exaggerated tendencies in the more conscious aspects of the personality. He felt that if appropriately attended to, dreams could reveal to the dreamer some of the universal truths about the psychological nature of man.

Despite their disparate descriptions of dreaming, all theorists who have addressed the psychological significance of dreams make three identical, if unarticulated, assumptions. First, they assume that dreams have meaning, i.e., that dreams are orderly, nonrandom events. Second, they assume that dreams are meaningful—that the content of the dream is overtly or covertly related to the waking, subjective life of the dreamer. Finally, they hold that dreams subserve some important psychological function and contribute to the adaptive capacity of the individual.

It has already been shown at the group level that dreams have meaning and are not random events (2). Psychologically differentiable groups of people have different dream content. Specifically, there are dream content differences between psychopathological and normal groups (trait differences). The dream content of individuals who are normal, schizophrenic, depressed, or have organic brain disease are distinguishable (3–5). Dream content differences have also been shown for males and females and for various age groups (6). Furthermore, dream content differences can also be demonstrated within psychopathological and normal groups as conditions change (state differences). The dreams of depressed patients before and after effective treatment are distinguishable (7), as are those of normal individuals before and after surgery (8).

From the vantage point of the clinician, however, the concern is not the behavior of groups but that of individuals. The clinician wants to know whether the dreams of an individual (normal or ill) are different from those of other individuals and whether these dreams reflect changes in the individual's condition. The clinician, like the dream theorist, wants to know if there are demonstrable trait and state differences at the individual level.

This inquiry is directed toward extending to the level of the individual the assumption that dreams have meaning. If dreams do have meaning (i.e., are orderly) at the individual level, they should be distinguishable among individuals (trait) and within an individual (state), as they have already been shown to be at the group level. More specifically, we should be able to distinguish the dreams of different individuals, the dreams of one individual on different nights, and the position of one dream within a series of dreams in one night.

METHOD

Two dream series were tested. The first series was from a group of 12 male college students, aged 20–25. These subjects slept for 20 consecutive nights in a sleep laboratory and had their dreams collected at the end of each of the first 4 REM periods of the night. The

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are with the Veterans Administration Hospital, 3200 Vine St., Cincinnati, Ohio 45220, where Dr. Kramer is Assistant Chief, Psychiatry Service, Mr. Hlasny and Mr. Jacobs are Research Assistants, and Dr. Roth is Research Psychologist. Drs. Kramer and Roth are also with the Department of Psychiatry, University of Cincinnati College of Medicine, where Dr. Kramer is Professor of Psychiatry and Dr. Roth is Associate Professor of Psychology.

second series was from a group of 11 hospitalized male schizophrenic patients, aged 40–55, who were being treated with phenothiazines. These patients slept in the sleep laboratory for 6 nonconsecutive nights, 3 early in their illness and 3 later, after they had improved (9). The schizophrenic patients were awakened for dream collection after 5 minutes of REM sleep for all REM periods of the night.

The dreams of both groups were recorded and appropriately coded for blind sorting tasks. To test the orderliness of dreams at the individual level, 3 sorting tasks were done for each dream series. In the first task, 3 judges were given 2 sets of randomly selected dreams. One set was made up of 75 dreams from 5 of the normal subjects (15 dreams per subject), and the second set was made up of 65 dreams from 5 of the schizophrenic patients (13 dreams per patient). The judges' task was to sort each set of dreams into 5 groups of equal size according to dreamer.

In the second task the 3 judges were given a group of 15 dreams for each of 10 college student subjects and 5 schizophrenic patients and were asked to sort the dreams of each dreamer into 5 nights of 3 dreams each. For 1 patient only 12 dreams were sorted, 3 from each of 4 nights.

In the third task the 3 judges sorted 50 sets of 3 dreams each from the college students and 34 sets of 3 dreams each from the patients. The task was to place each randomly ordered set of 3 dreams into the order in which the dreams actually occurred on a given night. If the 3 dreams selected came from a night with more than 3 dreams, the task was to place the 3 dreams in their order of appearance in relation to one another rather than in their sequential position.

The judges for the 3 tasks were of heterogeneous backgrounds and differed widely in their experiences with dreams. Judge 1 (M.K.) on both series was an experienced psychiatrist with many years of work in the area of clinical and experimental dream research. Judge 2 (G.J.) on the normal subject series was a second-year psychology graduate student, while Judge 2 (T.R.) on the patient series was an experimental psychologist who has had 5 years' experience in sleep and dream research. Judge 3 on both series was a fourth-year undergraduate student in psychology with 2 years' technical experience in sleep and dream research.

Data analysis was performed on all 6 tasks, 3 on normal subjects' data and 3 on patients' data, using chi-square tests. The expected or chance level was determined for each task by taking the mean of 10 random sorts.

RESULTS

Each of the judges was able to distinguish the dreams of individual college students ($p<.001$) and schizophrenic patients ($p<.01$) (see table 1). Clearly, the dreams of different individuals can be distinguished, whether the dreamers are normal or schizophrenic. This suggests that dreams have a meaning at the level of the individual.

TABLE 1
Frequency of Correct and Incorrect Differentiation of Dreams of Five Normal and Five Schizophrenic Subjects According to Dreamer

Item	Correct Judgments	Incorrect Judgments	Chi-Square	Significance
Normal subjects' dreams (N=75)				
Expected frequency*	22	53	—	—
Observed frequency				
Judge 1	53	22	88.057	$p<.001$
Judge 2	59	16	105.494	$p<.001$
Judge 3	59	16	105.494	$p<.001$
Overall	—	—	299.045	$p<.001$
Schizophrenics' dreams (N=65)				
Expected frequency*	16	49	—	—
Observed frequency				
Judge 1	26	39	8.290	$p<.01$
Judge 2	25	40	6.715	$p<.01$
Judge 3	25	40	6.715	$p<.01$
Overall	—	—	21.720	$p<.01$

* Mean of 10 random sortings.

The judges were able to sort the dreams of each of the 5 normal subjects at a level well beyond chance, but were able to do so for only 3 of the 5 schizophrenic patients. Although one can sort dreams from among normal subjects and among patients at a statistically significant level, the task is easier—i.e., the dreams are more distinguishable—among normal subjects than among patients.

In addition, each judge was able to sort correctly the dreams of both normal subjects ($p<.001$) and patients ($p<.001$) according to their occurrence on different nights (see table 2). This striking observation would seem to support the interpretation that dreams reflect day-to-day changes in the individual.

The judges were unable to sort the dreams of 2 of the 10 normal subjects into different nights at even the chance level. However, they were able to sort the dreams of all 5 schizophrenic patients into different nights at above the chance level. Although one can sort dreams from among different nights for individual subjects and patients at a statistically significant level, the task is easier for schizophrenic patients than for normal subjects.

None of the 3 judges was able to order the normal subjects' dreams into their correct position of occurrence within the night. The judges were differentially successful in placing the dreams of the schizophrenic patients into their correct relationship within the night (see table 3). Judge 3 was able to sort the dreams of schizophrenic patients into their correct order at a statistically significant level ($p<.01$) and Judge 1 was able to approximate significance ($.05<p<.10$). The problem in the normal subject population was a failure to correctly identify the dream in the middle position. Judge

3 attempted a second time to sort the normal subjects' dreams by position within the night but was still unable to do so at a statistically significant level.

The judges were, overall, unable to sort the dreams of a night into their correct position of occurrence. Although the sorting of schizophrenic patients' dreams suggests a positional effect, the most conservative conclusion would be that such an effect was not demonstrated. It seems worthwhile, however, to pursue the positional effect in further studies.

DISCUSSION

This study supports the assumptions of all depth psychologists that dreams are orderly, nonrandom events. Judges can successfully distinguish among the dreams of different people and among the dreams of one person on different nights. This is true for both normal and schizophrenic subjects, although at different levels of statistical significance.

The fact that an individual's dreams are distinguishable from those of another individual suggests that dreams reflect enduring traits of personality. It is probably this trait-related nature of dreaming that allows insights to be drawn about long-range aspects of the subject's psychic life from his dreams.

It could be argued that the ability to distinguish one person's dreams from another's relates not to the distinctiveness of the dreams but to individual differences in verbal style. In our opinion, however, the fact that a person's dreams of one night can be distinguished from those of another night argues against verbal style being the only distinguishing feature. If it were, verbal style would have to account for both inter- and intrasubject differences, even though, for the normal subjects, intrasubject differences were found in dreams only a few nights apart.

The fact that it was easier to sort the dreams of normal subjects than the dreams of schizophrenic patients suggested to us that the normal young male college student population was more diverse than that of the hospitalized male schizophrenic patients. This suggests that schizophrenics are more like each other and provides indirect support for the view of the commonality of the schizophrenic rubric. At least in their dream reports the schizophrenic patients were more similar to each other and therefore more difficult to distinguish. However, the patients' dreams may have been less distinguishable simply because the patients all shared a common and restricting environment—the hospital. An alternative explanation might be that the dreams of individual normal subjects were more homogeneous than those of individual schizophrenic patients. The dreams of the normal subjects were recorded during a 20-day period when there were no major state changes in their lives. The dreams of the schizophrenic patients, however, were recorded over a longer period and represented periods before and after treatment, with a corresponding change in psychopathological state. This change in state may have blurred the differences among schizophrenic patients and made sorting more difficult.

We believe that the reactive or state nature of the dream is reflected in the judges' ability to sort successfully the dreams of one night from those of another for both the normal subjects and the patients. To sort the dreams of the same person by night requires that the dreams of a given night have more in common with each other than with those of another night. Therefore, the state distinction reflected in dreams is not an especially enduring one and is probably measured in terms

of a day or days rather than weeks or months.

The fact that the schizophrenic patients underwent greater change across the dream collection period, which was longer than that for the normal subjects, might also in part explain why the dreams of the schizophrenic patients were more dissimilar on different collection nights than the dreams of the college students. This modest increase in the ability to distinguish among dreams of different nights for a schizophrenic patient would also argue for the reactive nature of a night's dreams—for the dream reflecting the state as well as the trait of the dreamer.

We do not feel that we have demonstrated the sequential interconnection of dreams of a given night, despite the statistical finding that overall we could sort the position of dreams within a given night for schizophrenic patients. Our failure to sort dream position within a night in normal subjects and the fact that our most accurate judge in placing the dreams of schizophrenic patients was unable to do so with the dreams of normal subjects leads us to our negative conclusion. It is possible that our not utilizing only sequential dreams compounded our difficulty in sorting the dreams correctly. Although our present data do not allow us to accept the notion of there being order among the dreams of any given night, we feel that this is a point worth pursuing.

We found it striking that the relative experience or inexperience of the judges in working with dreams did not have any effect on their ability to sort the dreams in any of the three tasks. The effective clinical use of dreams may be enhanced by the clinical experience of the therapist, but the ability to see connections among dreams appears to be unrelated to prior clinical experience. Apparently, the order in dreams is there to be seen for those who choose to look. One need not have an experienced eye.

It is our opinion that these observations not only support the assumption that dreams have meaning but also lend indirect support to the two other assumptions basic to any psychological theory of dreaming—namely, that dreams are meaningful and that dreams are functional. Our finding that the dream reflects the trait and state of the dreamer enhances the likelihood that the dream can be placed into the waking life of the dreamer and achieve meaningfulness. The apparently reactive nature of the dream that was shown by the judges' ability to distinguish one night of dreams from another gives the dream the flexibility needed to participate in the day-to-day psychologically adaptive activities of the dreamer.

Personality Disorder and Parietal Lobe Dysfunction

BY PAUL C. HORTON, M.D.

An inability to relate transitionally is a major feature of personality disorder. The developmental independence of transitional relatedness from verbal-symbolic growth, its orienting function, and the nature of its visual and tactile components support the conclusion that it is a function of the nondominant parietal lobe. Therefore it can be hypothesized that dysfunction of this area is the cerebral analogue of personality disorder. The fact that unawareness of illness ("anosognosia") in conjunction with grossly intact intellectual function is common to both personality disorder and minor parietal lobe dysfunction further supports this hypothesis.

THE INABILITY to relate transitionally has proven, in my experience, to be the psychopathological cornerstone of personality disorder. In this paper I will first briefly describe the psychological characteristics of transitional relatedness and then consider its possible neurological analogue and the inferences that can be drawn from its absence.

TRANSITIONAL RELATEDNESS

The transitional object has been described as "the infant's first possession, a blanket or toy which he holds and manipulates on going to sleep and in times of distress" (1, p. 93). Winnicott (2) described the transitional object as any of a limitless number of soothing objects and experiences—a blanket, teddy bear, soft or hard toy, an infant's babbling, even a tune. Any idea, concept, or thing can be "transitional" provided that it is experienced in the "third or intermediate area" (2).

For the child the transitional object is "a sedative which always [works]" (2). Busch and associates stated: "This functional value . . . as a soother . . . is something that is agreed upon by all" (3). A child who is too suddenly deprived of his treasured soother will become disconsolate, have difficulty falling asleep, and may even mourn its loss.

The nearly ubiquitous ability to personalize and make an external object such as a blanket or teddy bear internally meaningful is a developmental milestone. In a previous communication (4) my associates and I stated that this ability

> takes its origin, in part, from the time when a child is able to imbue a toy or other concrete object with the life he feels stirring inside of himself. . . . In this way, *that* teddy bear becomes *his* teddy bear. Unique in the world and irreplaceable, it is the psychological area of the personal universe where the external reality of cloth, stuffing and buttons becomes inseparably interwoven with the life of its owner.

Psychological maturity—even the "ultimate stages of a human being's capacity for cultural experience" (4)—results partially from and confers subtlety and complexity to transitional relatedness (2, 5–7).

The Orienting Function of the Transitional Object

An important aspect of transitional relatedness is its orienting function. To be oriented means to be adapted to a particular thing or situation. Psychiatrists and neurologists customarily state that a person is oriented when he is aware of person, place, and time. The neurologist may also use this term to denote other kinds of awareness. He may mean that the patient can distinguish left from right, construct block designs, and copy test figures.

The infant or small child, however, is not oriented in the customary or some of the more specialized ways described above. The sense of past and future is entirely lacking in infancy and only weakly developed at age 3. Similarly, "place" other than home is recognized only after the first year of life. Infants and small children cannot, of course, distinguish left from right or correctly copy designs.

In spite of these characteristics, we do not ordinarily refer to infants and small children as "disoriented." The 6-month-old infant is oriented when he is able to recognize "mother." This is the earliest and most basic interpersonal orientation. The mother *is* the infant's world. As Spitz said: "From the beginning of life it is the mother, the human partner of the child, who mediates every perception, every action, every insight, every knowledge" (8, p. 101).

The mother is normally much more than a familiar face or a mere female parent. She is the child's primary soother. Through her come all good things.

The child is able to leave the mother's bosom when he can find something of her nurturance in the world about him. Without this ability he is disoriented; the

Dr. Horton is in private practice in Meriden, Conn. He is also Assistant Clinical Professor, Department of Psychiatry, Yale University, New Haven, Conn. Address reprint requests to 41 Mattabasset Dr., Meriden, Conn. 06450.

world is frighteningly foreign. Nature has conferred on the normal child a special capacity for transitional relatedness that permits exploration and eventual separation. The child can conjure up the soothing qualities of mother by means of inanimate objects, concepts, ideas, and other human beings. The transitional object, as the mother surrogate, is the child's compass and convoy to the unfamiliar. Clutching his stuffed animal, reciting his favorite prayer, or contemplating the powers of his latest superhero, he is nearly always "at home."

PERSONALITY DISORDER

The following cases illustrate disorientation and other salient features of personality disorder. Such exemplification is necessary because this diagnosis, even when made by experienced psychiatrists, continues to have low interrater reliability (9).

Case 1. A 29-year-old woman was first seen a few days before the birth of her second child. Her obstetrician was at his "wit's end" because of her chronic complaining. She had already alienated her previous obstetrician and several other physicians with perpetual carping about their failure to relieve her many aches and pains. Her husband was also getting fed up. The circumstances were reminiscent of the patient's early life, when her parents told her, "No matter what you have you're never satisfied." All potentially nurturing figures were resented by the patient and were relegated to caretaker status. Psychological testing verified the absence of psychotic or neurotic conflicts and confirmed a diagnosis of inadequate personality. She had no history of transitional relatedness.

The patient's 9-year-old daughter had, in contrast, both a teddy bear and a "friend blanket." I asked her what ideas she had about why her daughter had such attachments and she had none. She stated:

> You see, my mother made me afraid of everything. I can remember her riding the school bus with me when I didn't want to go to kindergarten. When I was 12 or 13 years old she was always after me about locking the doors at night and didn't want me to stay home alone. I think because of my parents I never had many friends. I didn't like being alone but I hated crowds. Even today I don't like it if the neighbors bring their kids over. I can only take it for about 10 minutes and then they start getting on my nerves. I can't keep up with what is going on when there are a lot of people around. I never felt secure. . . . The difference between me and my daughter is that she can feel secure . . . her teddy bear makes her feel at home. It gives her a sense of routine. She doesn't feel strange when she has it with her.

In this case we see how lost and frightened individuals with personality disorder are from early life. They experience all human beings with equal impersonality. One caretaker is as good or bad as another, and all are resented. The soothing qualities of mother are neither perceived nor internalized. Hence, these persons grow up feeling they are owed something, although they have no idea what it is. Responsibility is externalized ("My mother made me afraid, . . ." "Because of them, . . ." "My doctor didn't . . ."). This basic disorientation, rooted in infancy, causes them to stumble "through the world wrapped in [their] separateness, as though in an insulator, touched rarely and never moved by [their] fellow man" (4).

Case 2. The mother of a 9-year-old boy stated, "We can't get him to go along with what we want." The patient was referred for evaluation after he threatened his 13-year-old brother with a knife. The parents were alarmed by the savageness and seriousness of intent of the attack. They said that he "always seemed to have a mean streak," was "easily upset," and would "have to get even for anything that was done to him." He was "always more clumsy" and "harder to reach" than his siblings. His fourth-grade teacher said, "There is something missing in him that is hard to put a finger on." Unlike his siblings, he had no history of transitional relatedness.

The patient revealed feelings of inadequacy, loneliness, and isolation. The psychologist stated that "parental figures are not seen as nurturing and a source of strength." He frequently portrayed sadistic superhuman creatures from outer space in therapy.

The patient performed relatively poorly on visual-motor and spatial organization tasks. Prior to therapy his scores on the verbal and performance portions of the Wechsler Intelligence Scale for Children were 116 and 75, respectively. After 6 months of therapy designed to increase his ability for transitional relatedness his scores were 112 and 91. The relevance of these results will be discussed later.

Unable to permit psychological soothing or to develop the ability for psychological self-soothing, he had never emotionally perceived "mother." Her essence, i.e., the ability to soothe and nurture, had eluded him. Therefore he could find no mother surrogates. There was no valid basis for transition, and he was lost in the "outer space" of his inner mind.

THE NEUROPSYCHOLOGY OF PERSONALITY DISORDER

The following hypothesis will be explored in this section: 1) An inability or incapacity for transitional relatedness is the psychopathological cornerstone, the necessary (albeit not sufficient) condition of personality disorder (4). 2) The locus of transitional relatedness is the right (nondominant) hemisphere; therefore personality disorder is related to or caused by, in part, a disturbance of the right hemisphere. 3) The fact that unawareness of illness in conjunction with generally intact intellectual functions is observed in both personality disorder and nondominant parietal lobe dysfunction suggests that there is a specific relationship between these syndromes.

Transitional relatedness is usually first manifested during the fourth to twelfth months of life (2). Thus it ordinarily predates all but the sensorimotor state (10, 11) of verbal-symbolic development. Moreover, verbal symbolic maturity can occur, as it does in personality disorder, without the ability for transitional relatedness. Neither of these developmental milestones is,

therefore, a necessary condition for the appearance of the other.

According to the "law of progressive lateralization of functions" (12, 13), developmentally independent and important psychological structures might be expected to be located in opposite hemispheres. This law posits a hemispheral division of labor in which the "left (dominant) hemisphere (in right handers) begins to play an essential role . . . in cerebral organization of all higher forms of cognitive activity connected with speech . . . whereas the right (non-dominant) hemisphere either begins to play a subordinate role . . . or plays no part whatsoever in their course" (12, p. 78). Since verbal-symbolic behavior is a function of the posterior two-thirds of the left hemisphere in 97% of the population (13), it is reasonable to speculate that the right hemisphere is the cerebral correlate or locus of transitional relatedness, which is a nonverbal ability.

However, we may go beyond sheer speculation. The orientational role of the right hemisphere is well established. It is known, for example, that the right hemisphere is essential to a "holistic, gestalt mode" of perception (14). A patient with a disturbance of the nondominant parietal lobe may be unable to orient himself in space, reproduce constructions, or recognize objects. Disturbances of body schema also occur (15).

The orientational function of transitional relatedness bears an anatomical relationship to these orientations. Tactile recognition—a major determinant in the selection of the infantile transitional object (3)—is a function of the right hemisphere. Recognition of the mother's face—a precursor of infantile transitional relatedness—is also a function of the right hemisphere (14). The relatively poor performance on visual, motor, and spatial organization tasks by the 9-year-old personality disordered boy described earlier and observed by me in several other adult and child cases supports this inference.

In addition to disorientation, lack of awareness of illness is common to both personality disorder and dysfunction of the nondominant parietal lobe. As regards personality disorder, Freedman and associates stated that "the affected person does not think of himself as ill or deviant" (16, p. 373). Eaton and Peterson said: "Except when there is external stress, either coincidental or in reaction to the patient's behavior, anxiety is absent. Other subjective complaints are rare; when present, they are usually rationalizations or conscious efforts to excuse failure" (17). Derdeyn said: "The personality disordered person's maladaptive behavior is experienced as a normal, natural part of him, and he does not usually have feelings of doubt or of having made mistakes" (18). The following case illustrates this feature of personality disorder.

Case 3. A 16-year-old boy who had been a severe disciplinary problem from early childhood was referred for psychiatric evaluation by the public school system. He had been physically assaultive toward peers, teachers, police officers, and relatives. School officials had become fearful of setting limits because of his "bad temper." He had few friends and did poorly in school. He acknowledged that it would be very difficult for him to obtain a job without a diploma, but he angrily rejected a truncated school day designed to minimize violent outbursts. Neurological and EEG exams were within normal limits. The diagnosis was explosive personality disorder.

The patient could recall no transitional objects. His mother was also unable to recall soothers or favorite toys used by her son, although she described extensive transitional object usage by his siblings. He showed no insight into his disturbed behavior; for example, he remarked that, "if they [teachers, peers, etc.] give me bad luck, I give it back." He refused treatment, asking incredulously, "What for?"

The lack of awareness of psychological disturbance shown by those with personality disorders is conceptually isomorphic with "anosognosia," a symptom of nondominant parietal lobe dysfunction. The congruence is striking:

> Every agnosic patient, regardless of the modality involved, is incompletely aware of his deficit; hence he neglects and denies it. The neglect, denial and imperception are usually directly proportional to the severity of the defect. Though he may know that something is wrong, he cannot define it, and when he is most severely affected he does not even recognize that he is ill. (19, p. 44)

Apposite to the present thesis is that anosognosia is a *defining* minor parietal lobe sign:

> It is not the gnostic disorders just described which are of the greatest importance . . . but the general *perception by the patient of his own body and his own personality*; accordingly, by far the most important symptom of a lesion of the right hemisphere is the remarkable *absence of perception by the patient of his own defects*, a condition known for many years in clinical practice and to which the name *anosognosia* has been given. (12, p. 167)

Both personality disordered individuals and patients with a parietal lobe deficit are rigidly unable to recognize their illness. In neither case is this ignorance of illness usually amenable to improvement by major tranquilizers or vigorous conventional psychological approaches. Psychological conflicts do not appear to underpin the unawareness.

Compatible with identification of dysfunction of the nondominant parietal lobe as the cerebral analogue of personality disorder is the presence of grossly intact intellectual functions in both conditions. Luria stated that "right handed persons with a lesion of the nondominant right hemisphere exhibit no disturbances of speech, writing, reading and arithmetic . . . and their understanding of logical-grammatical structures, as well as their formal logical operations, remain unimpaired" (12, pp. 163–164). Correlatively, personality disordered persons exhibit normally distributed intelligence (16, 20).

Less specific characteristics of personality disorder

consonant with a parietal lobe analogue are pervasively poor judgment ("deeply ingrained maladaptive patterns of behavior" [21, p. 41]) and concreteness. Personality disordered persons lack active interests, aims, attachments, values, or goals that extend beyond the most immediate concerns of their own lives. They show a cognitive style that is "inevitably dominated by the present" (22) and, as such, is correctly labeled "concrete." Although they may do well at proverb interpretation and similarities, they manifest concreteness in the highest, distinctively human functions such as "the capacity to think creatively, to deal effectively with new and complex problems, and to love and care for others" (23, p. 10). Such concreteness is a well recognized sign of organic brain syndrome.

DISCUSSION

The hypothesized relationship between personality disorder and nondominant parietal dysfunction is preliminary, tentative, and, above all, incomplete. For example, the effects of familial and cultural determinants, pathological physiology, the endocrine milieu, metabolic enzyme systems, possible genetic contributions, and other potentially relevant psychobiological parameters on the personality disordered human being have not yet been explored. In addition, space limitations do not permit a consideration of alternative cerebral loci.

Many questions remain about personality disorder and lack of transitional relatedness. Is personality disorder a function of an inability or incapacity to relate transitionally? If inability is at issue, how can growth of transitional relatedness be stimulated? If incapacity is the source, what compensatory mechanisms can be elicited? Can neurological as well as psychological measures be employed to either stimulate or compensate for lack of transitional relatedness? Do critical periods exist for the acquisition of transitional relatedness, as is the case with language development (24)?

Although previous studies of neurological parameters of "conduct," "character" and "personality" disorder, "psychopathic personality," "vulnerable personality," etc., have not been reviewed in this article, they add little to the present thesis. For example, it is far from clear exactly what is being held to relate to the electrical activity of the brain in numerous studies (25).

One can hope that one consequence of greater understanding of personality disorder will be an enhancement of realistic sympathy and humane regard for its victims. Lacking an important dimension of human experience, these rigidly constricted and isolated human beings, who show chronically poor judgment in matters of love and work, view ordinarily meaningful social life as outsiders. Like my 9-year-old patient, they feel themselves to be creatures from outer space. They hope that they are powerful enough to manage. Although they are held mentally competent and legally responsible (witness the recent death sentence of a 15-year-old Florida boy for the rape-slaying of a 12-year-old girl), they have no valid concept of choice and responsibility. The recognition of a concurrence of several serious psychoneurological deviations from the normal that result in impairment of the capacity for survival and efficient functioning should permit us to consider the possibility that personality disordered individuals are truly ill.

Psychiatric Effects of Prolonged Asian Captivity: A Two-Year Follow-Up

BY RICHARD C.W. HALL, M.D., AND PATRICK T. MALONE, M.D.

The authors have been following a group of 6 prisoners of war and their families since the men were returned from North Viet Nam. They found that most of the men experienced cognitive, social, work, emotional, and family difficulties during the first two years after their return. However, most of these problems were resolved after two years, and there was no evidence of the concentration camp syndrome, homicidal or suicidal behavior, violent physical aggression, impotence, fugue states, psychosomatic disorders, or major psychiatric illnesses in any of the men. On the basis of their findings, the authors make recommendations for future reentry programs.

MORE THAN TWO YEARS have passed since the release and repatriation of 566 Americans held prisoners of war (POWs) in North Viet Nam. Initial reports indicated that the men were in better than expected condition. The concentration camp syndrome seen frequently in prisoners held by the Nazis has not appeared. Much of the research on man's reaction to the stress of captivity (1–15) seems applicable to our released POWs from Viet Nam.

Information released by the Department of Defense in May 1973 (16) indicated that of the 566 returned POWs, only .7% were diagnosed as having a psychotic disorder, 1.9% as being mildly to moderately depressed, and 2.5% as having an adult situational reaction. The relative absence of psychiatric diagnoses in 1973 suggested that reintegration into the social, family, and community framework would be a straightforward process for these men. This paper describes the effects of captivity on the social reintegration of 6 of the 566 POWs.

METHOD

We followed 6 returned POWs (1% of the POW returnee population) and their families for two years. In all cases we had known the families for at least one year before the men's return. Prereturn problems in these families and the relationship of the initial symptoms to the gross stress model of captivity have been reported elsewhere (6, 7). Data were obtained from psychiatric interviews, family contacts, individual and group meetings, and medical and work records. Comparative group data were obtained from the Center of Prisoner of War Studies, San Diego, Calif. The men and their wives and children were seen individually, in small groups, in large groups, and in social situations. We each made independent evaluations of family dynamics and symptoms and then validated these evaluations together.

All of the returned POWs were career military pilots who had been imprisoned for a minimum of five years in the Hanoi area. The 6 men shared certain personality features: they were assertive, competitive, confident, emotionally suited to flying, action-oriented, role-dominant, systems-oriented professional officers who minimized their own dependency needs. All expressed great body awareness and were involved in extensive physical conditioning.

RESULTS

Cognitive Function

All of the men showed cognitive changes that they, their wives, or we perceived as important (see table 1). None of them, however, was grossly incapacitated, and we observed no organic brain syndrome. The general clinical picture in all 6 men was one of adaptive mental slowing, manifested by reduced rates of cognitive processing and a temporary inability to assimilate new material. Confusion was inferred from flooding of awareness and indecisiveness of action. Disorientation to time was inferred from a distorted perception of the passage of time. Diminished visual-motor perception was inferred from difficulty with driving a car. Changes in cognitive function were more apparent and disconcerting to the POWs' families than to the men themselves.

Depressive Symptoms

The depressive symptoms observed in 3 of the men were reactive in type and ranged from mild to moderate in severity (see table 1). In no case did a picture of endogenous or agitated depression develop. No suicidal ideation was reported.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Hall is Assistant Professor of Psychiatry, University of Texas College of Medicine, Houston, Tex. 77025, and Director, Clinical Research Unit, Texas Research Institute of Mental Sciences, Houston, Tex. Dr. Malone is in private practice in Atlanta, Ga.

TABLE 1
Problems of 6 Returned POWs Perceived as Important by the POWs, Their Wives, and/or Their Physicians

Item	Number of POWs, by Person Who Perceived Symptom as Important			
	POW	Wife	POW and Wife	Physician
Symptoms of cognitive dysfunction				
Confusion (N=4)	1	2	2	2
Disorientation to time (N=4)	1	2	1	1
Diminished visual-motor perception (N=5)	0	4	1	3
Diminished memory function (N=5)	2	1	2	4
Diminished concentration span (N=4)	2	1	1	3
Depressive symptoms				
Insomnia (N=5)	0	1	4	5
Disturbance of appetite (N=2)	0	2	0	2
Diminished sexual function (N=0)	—	—	—	—
Suicidal ideation (N=0)	—	—	—	—
Clear psychophysiological reactions (N=0)	—	—	—	—
Substantial physical disability (N=1)	0	0	1	1
Identification with the aggressor (N=2)	0	0	0	2
Intermittently depressed mood (N=3)	1	0	2	3
Cyclical thinking (N=3)	1	0	2	3
Episodic tearfulness (N=3)	1	0	2	3
Feelings of inadequacy (N=3)	1	0	2	3
Excessive fatigue (N=3)	1	0	2	3
Emotional symptoms				
Marked mood shifts (N=2)	0	2	0	2
Paranoid ideation (N=1)	0	1	0	1
Hoarding behavior (N=1)	0	1	0	1
Aggressivity (N=2)	0	2	0	2
Depression (N=3)	0	1	2	3
Fatigue (N=2)	1	1	0	0
Guilt (N=4)	4	0	0	4
Phobias (N=0)	—	—	—	—
Defensive ritual (N=1)	0	0	0	1
Anger aroused by sight of certain Orientals (N=1)	0	1	0	1
Episodes of anxiety (N=3)	1	1	1	3
Fear of crowds (N=4)	2	0	2	4
Flashbacks of camp experiences (N=3)	3	0	0	3
Intrusions into awareness (N=3)	3	0	0	3
Social functioning				
Deterioration of social habits (N=2)	0	2	0	2
Verbally aggressive; inappropriate social behavior (N=1)	0	1	0	1
Family relationships				
Takes dominant role (N=5)	0	0	5	0
Takes passive role (N=1)	0	1	0	0
Jealous of wife (N=2)	0	2	0	2
Suspicious of wife (N=2)	0	2	0	2
Excessively controlling of wife (N=1)	0	1	0	1
Has conflicts with children (N=2)	0	2	0	2
Lacks language skills (N=1)	1	0	0	1
Lacks interpersonal skills (N=4)	2	2	0	4
Work adjustment				
Fear of inability to function at first job after return (N=3)	1	0	2	0
Indecisiveness (N=3)	2	1	0	0
Anger directed at military service (N=1)	1	0	0	0

The mood shifts of 2 of the men were bipolar and somewhat unusual: one mood was characterized by purposeful "doing" activity coupled with enthusiasm, planning for the future, increased participation in the family, and emotional closeness with family members; the other mood was characterized by withdrawal from the family, dissociation from group activity, a pessimistic attitude toward the future, and increased hostile and accusatory behavior directed toward family members. The men who experienced these symptoms could move from one mood to the other in a matter of minutes. The swings were triggered by what the men perceived as rejection by their wives, who responded to the swings initially with caring, then with anger, and finally with emotional withdrawal. As the women increased their emotional distance, the children also withdrew from their fathers and sided with their mothers.

The insomnia that occurred in 5 of the 6 POWs shortly after their return tended to abate during their first month home. One man experienced sleep-disrupting nightmares clearly related to his captivity experience, and 2 others experienced non-sleep-disrupting catastrophic dreams centering on themes of punishment and captivity.

Depressive symptoms abated within the first year. Three of the men continued to have nightmares after being home for two years. Four men expressed guilt related to having been separated from their families and concerning thoughts or reactions they had while in captivity. They did not tell their families about this guilt and discussed it openly with us only after a relationship of trust had developed. The wives of these men seemed totally unaware of their husbands' feelings of guilt.

Substantial anxiety was present in 3 of the POWs and seemed related to the guilt they expressed. The episodes of overt anxiety had subsided nine months after their return. Although no phobias per se were present, 4 men were judged to have a fear of crowds and 1 man developed the defensive ritual of formally pledging allegiance to a small American flag every day on arising and retiring. One of the men reported the sudden emergence of anger on encountering Orientals whose facial features or mannerisms seemed similar to those of his captors. He never directly expressed this anger and therefore no confrontations resulted. Paranoid ideation was seen in 1 individual, but this had been a personality trait before this man's captivity experience. One man evidenced marked and inappropriate hoarding behavior during the first six months after his return. The aggressivity noted in 2 of the POWs was not judged inappropriate and never entailed substantial physical violence.

Three of the men reported flashbacks of camp experiences as well as intrusive thinking similar to that described by Horowitz and Becker (9, 10). The flashbacks were episodes during which the men felt that they were physically still in captivity in North Viet Nam. These were of short duration and were followed by cognitive awareness of the misperception. The intrusive thinking was characterized by the sudden projection into consciousness of events that were recognized as having occurred in the past.

Emotional Symptoms

We believe that the emotional symptoms of these men (see table 1) were more affectively charged and anxiety producing for the couple than the cognitive symptoms and were therefore handled by mutual avoidance. Emotional symptoms were recognized and considered important by both husband and wife less often than cognitive symptoms. However, recognition of these symptoms by one or the other spouse was frequent. The fear that such symptoms represented mental illness was expressed by either the husband or the wife in 5 of the 6 families. The husbands tended to be more concerned about intrapsychic processes, while their wives expressed more concern about symptoms affecting interpersonal behavior. The couple could easily relate cognitive symptoms to captivity, but they were unable to view emotional symptoms from the same perspective. The wives felt that cognitive function would return in time, but they clearly desired assistance in dealing with emotional disturbances, which they perceived as more devastating.

Social Functioning

Two of the men exhibited marked disregard for conventional social customs (see table 1). They ate very fast, scraped food from their plates and those of other family members, walked about the house in their underclothing, left the bathroom door open, etc. They did not initially perceive this behavior as unusual. At first their wives said nothing about this behavior, but after two to three weeks they began to confront the men about it. The behavior abated within six months. Four of the men had difficulty understanding the affective content of language and in processing its nonverbal component. This symptom persisted for six to nine months after their return. Disordered social functioning was viewed as important by the wives more often than by the POWs and was not an area of mutual discussion.

Family Relationships

Readjustment difficulties seemed most manifest in family relationships (see table 1). Five of the 6 returnees resumed their dominant roles after a short period of dependency. For about two to three months they relied on their wives to reorient them to the changes that had occurred in the family. They then suddenly reasserted their control over the family. Women who had been handling finances, making decisions about the children, and purchasing homes were expected to return these "executive functions" to their husbands. Three of the women expressed resentment at their husbands' taking control of the children. One stated that it was "as if an outsider had come in and begun ordering them about." The men tended to assume control of the male children but often left the female children to their wives.

Three of the 6 women set a definite deadline of less than a year for improvement of the family difficulties. These women saw divorce as a solution to interpersonal difficulties if this deadline was not met. The time limits were clearly communicated to the men, but the changes needed to fulfill the women's expectations of improvement were not clearly communicated. Only 2 of the 6 couples viewed their marital relationship as satisfactory at the end of the first year after the POWs' return. By the end of the second year, 4 marriages were stable, 1 had terminated in divorce, and 1 was still in crisis. The women attached far more importance to the family difficulties than did the men, who were often unable to perceive them at all.

The women ranked their problems in the following descending order of severity: 1) emotional isolation

from their husbands, 2) inability to feel important to their husbands, 3) the husband's emotional "deafness" to the wife, 4) difficulty in sharing control of the children, 5) role reversal from their previous pattern, 6) social isolation, and 7) fear of emotional breakdown in their husbands, their children, or themselves. These issues are reflected in the divorce rate of 26.9% reported for the whole POW group two years after return.

Work Adjustment

Three of the men expressed apprehension about not being able to perform well at their first postreturn jobs (see table 1). The strangeness of a new task, lack of previous experience with the duties, difficulty with memory and concentration, and the fear of failure focused on the issue of job performance. All of the men spent long hours "studying" their new jobs and continually assessing their performances. Four men were unsure whether they would be able to satisfactorily return to work, and 2 felt that their indecisiveness would preclude satisfactory adjustment. The men were much more concerned with this aspect of their lives than were their wives. Work represented the first external assessment of their functional capacity and thus was equated with their self-worth. The difficulties with job performance diminished during the first six to nine months. All of the men actually functioned quite well on their jobs from the outset.

CONCLUSIONS

Our findings do not support a low incidence of psychiatric morbidity for POWs from Viet Nam. Most of the 6 men we studied had some social, work, emotional, and family difficulties. Each area of difficulty seemed specific and followed its own course of onset, impact, and resolution.

Cognitive difficulties were most pronounced during the first three months after return, were resolved without specific intervention, and were easily dealt with by the families. Social problems were most pronounced from the third through the sixth month, were not considered important by the men, but were matters of critical concern for the women. The return of structured family roles was contingent upon resolution of these problems.

Self-imposed and overdetermined standards of work performance represented an important stress for the men from the third through the ninth month after return. After this they were able to function like their peers. The third through the ninth month was also the time when the men felt more uncomfortable in non-POW, nonmilitary social groups.

Emotional factors were present predominantly from the third month through the end of the first year after return and resolved gradually after that. Episodic sleep disturbances were still present in 2 men after two years. Family difficulties tended to resolve during the second year after return.

A temporal sequence of reintegration appeared in all 6 of these families. Reparative work and social functioning could not begin until cognitive clearing had occurred. Emotional factors could not be resolved until there was a stable social and professional role definition. Family problems could not be resolved until adequate time had passed for the wife to feel comfortable with her husband's emotional state.

At the end of two years we saw no evidence of the concentration camp syndrome, homicidal or suicidal behavior, violent physical aggression, impotence, fugue states, psychosomatic disorders, or major psychiatric illness in the 6 men studied. They are currently functioning well at work, have reintegrated themselves socially, and have resolved most of their family problems.

RECOMMENDATIONS

A five-year follow-up of these men may reveal additional time-determined behavior patterns. It was initially difficult to evaluate these men thoroughly and to intervene psychotherapeutically because of the suspicion, distorted self-concepts, lack of trust, and guilt that they harbored. We found that having made contact with their wives provided the best means of reaching these men and helping their families. None of the men would have "submitted to psychiatric interrogation" if their wives had not shown a sense of trust in us. In any future reentry program for POWs, contact with the prisoners' wives should be actively established before the men return.

Psychiatric symptoms in our 6 returning POWs were not readily apparent to casual observation and were not initially reported by them. Many of the men actively tried to conceal painful reactions from the psychiatric team who initially saw them. Although their symptoms persisted, the men became amenable to treatment only because of the development of family problems.

Clarification of their role and self-image, passive-aggressive anger, fear of dependency, inability to trust, and guilt were important therapeutic issues for these men. They stated that direct therapist involvement in work situations and the resolution of questions about their job performances were useful.

Role reversal, inability to share control over the children, feelings of uselessness and inadequacy, social isolation, and fear of emotional breakdown were important therapeutic issues for the wives.

We believe that the following assumptions and programs would be useful in the creation of any future reentry programs:

1. Psychiatric symptoms will be present in most of the returning POWs.
2. Psychiatric symptoms are directly related to the gross stress of captivity.
3. Psychiatric symptoms are best viewed as normal reactions to abnormal situations.

4. Returning POWs will have difficulty in seeking psychiatric help.

5. Marital and family difficulties are likely to occur after the POWs return. They represent the best opportunity to engage POWs in treatment.

6. Severe intrapsychic distress may not be apparent, but it can be readily inferred from behavioral patterns.

7. Establishing a close therapeutic alliance with their wives and children before the POWs return greatly facilitates the families' using helping agencies after the return.

8. Homecoming constitutes an important additional stress for POWs and should be handled slowly, if possible.

9. Reentry group workshops should be held before family reunion. They should deal with the sharing of prison experiences, descriptions of panic reactions, and the clear acceptance of captivity behavior by authority figures.

10. POWs should be briefed before reentry on the current status of their families and on any general changes that have occurred at home.

11. Information that can diminish cultural shock should be imparted slowly to the POWs before their return.

12. Reentry should not be made more stressful by the POWs' making massive public commitments immediately.

13. The POWs should be oriented to their new jobs; there should be a nonthreatening liaison person on the job to whom they can turn for information.

14. Central liaison figures to coordinate medical, psychiatric, and social care for the POW/MIA family should be appointed at military hospitals. These individuals should have clearly defined credibility by being formally allied with a central POW center and should be interested in this kind of position.

15. All psychiatric records of returning POWs should be strictly confidential. They should not be a part of routine health records.

16. Careful consideration of the consequences on the whole group of POWs should be given when court martial procedures are initiated against a POW.

17. Physical rehabilitation and medical and dental treatment programs should be well under way before family reunion.

Management of Interpersonal Issues in Systematic Desensitization

BY DAVID L. BRAFF, M.D., MARJORIE RASKIN, M.D., AND DAVID GEISINGER, PH.D.

The authors use the management of typical clinical problems that arise during systematic desensitization as a model for the analysis and solution of problems associated with behavior therapy techniques. Three main problem areas are considered: initiation of the technique, therapist and patient difficulties, and therapeutic decision making. The discussion is designed primarily to help therapists with varied backgrounds to deal with clinical issues that arise in the application of behavior therapy techniques such as systematic desensitization.

IN THE COURSE of teaching therapies based on learning theory, we have noted a paucity of information on the management of interpersonal issues that arise during the practice of such behavior therapy techniques. In the past, some behaviorists denied that interpersonal issues such as resistance and transference occur in behavioral work and considered these constructs a "popular alibi" (1) used to justify therapeutic failures. Many behaviorists now acknowledge that these issues play a critical role in behavior therapy (2, 3), and several have begun to describe these phenomena in learning theory terms (4–6). As part of this broadening perspective, there is increased interest in integrating learning theory and psychoanalytic principles (7).

Much of the behavioral literature, however, ignores interpersonal issues, leading to a glib assumption of efficacy of these techniques. This induces some therapists to reflexly reject therapeutic claims and others to try a technique like systematic desensitization (SD) in the naive hope of quick, mechanical cures. The latter approach is doomed, since outcome, even with the simplest behavioral techniques, depends on complex interpersonal variables (8–10).

The purpose of this discussion is to place traditional systematic desensitization and its attendant problems in a framework of social learning theory that will be useful to therapists with varied backgrounds who wish to use SD in their clinical work. We will review problems that arise in three major areas: initiation of SD, problems of therapists and patients that interfere with SD, and therapeutic decision making. Some of these principles can be extrapolated to other behavioral techniques (e.g., operant ward management and flooding), but we will confine our discussion to systematic desensitization. Although we have chosen to discuss traditional SD as described by Wolpe and Lazarus (1), we recognize that recent research has suggested that in vivo exposure, without relaxation or hierarchies, may be sufficient for successful therapeutic outcome in desensitization (11).

Dr. Braff is Chief of Inpatient Services, University Hospital, and Assistant Professor in Residence, Department of Psychiatry, University of California, San Diego, School of Medicine, La Jolla, Calif. 92037. At the time this work was done, Dr. Braff was Assistant Clinical Professor of Psychiatry, Langley Porter Neuropsychiatric Institute, University of California, San Francisco, where Dr. Raskin is Assistant Professor in Residence and Dr. Geisinger is Assistant Clinical Professor of Psychology.

INITIATION OF SYSTEMATIC DESENSITIZATION

There are a number of issues that can lead to clinical management problems if they are not dealt with as they arise in the early stages of SD.

First, the therapist must have a sound technical knowledge of SD and its major components—relaxation training, hierarchy formation, and pairing hierarchy images with relaxation (12).

Second, the therapist should be aware that unrealistic positive or negative expectancies held by the therapist, the patient, or both, can interfere with SD (13). Unwarranted therapist optimism sometimes results when an inexperienced therapist naively accepts poorly documented claims of facile "cures." Such optimism can also result from cultish allegiance to the behavioral school. Attitudes of this nature are inevitably transmitted to the patient, who may have his own store of distorted positive expectancies based on conditioned dependency and rescue fantasies. This unrealistic optimism on the part of therapist and patient easily changes to reactive negative expectancy (with possible disruption of the therapeutic alliance) when the usual treatment problems occur. Unrealistic negative expectancies may also occur when the therapist, discouraged about the patient's prognosis or progress in traditional treatment, fails to evaluate the patient specifically as a candidate for SD. In this situation SD can be seen as a desperate last resort rather than a treatment of choice.

A third area for examination is the patient's attitude toward systematic desensitization. The therapist should be alert to the possibility that the patient will consider SD a "second class" treatment designed to suppress symptoms rather than to "cure" them. This is especially true when SD is introduced into insight-oriented therapy that the patient has experienced as beneficial. Patients may attempt to sabotage the SD in or-

der to return to the therapy that is more immediately reinforcing. In these circumstances, it is often useful to continue the (usual) treatment modality in combination with the SD, since this often enhances the power of both approaches. A contraindication for combining treatments is the therapist's judgment that interaction with the patient around issues related to SD will undermine his ability to serve in his more traditional therapeutic role (e.g., by disrupting the emergence or resolution of transference). For example, a therapist might be less able to effectively interpret a paranoid patient's fear of being controlled if the therapy included a traditional, highly directive SD. In many circumstances, however, effective desensitization may outweigh the risks related to combining therapies. (We will discuss this issue further.)

Treatments can, of course, be combined by using two different therapists. This is a viable alternative when the two therapists can work together with mutual respect. Close collaboration is necessary to avoid placing the patient in the damaging position of having two therapists with mutually exclusive explanations of the problem and its resolution.

A fourth area that must be dealt with at the outset of SD is the therapist's comfort in his (new) role. Therapists who are inexperienced in behavioral techniques may feel foolish and uncomfortable as they begin doing something that seems strange, mechanical, and of unproven worth to them personally. Therapists may deal with this discomfort by gradually slipping back into their familiar therapeutic techniques. When this is a persistent problem, we suggest that a designated time slot be allocated to systematic desensitization and that this time be used exclusively for SD or for problems directly related to SD. Other treatment techniques can be carried out in another time slot or can be made contingent on the completion of the behavioral work (i.e., a contingency contract).

THERAPIST AND PATIENT PROBLEMS THAT INTERFERE WITH SYSTEMATIC DESENSITIZATION

The second major area around which clinical management problems center is related to certain characteristics of therapist and patient.

Therapist-Related Problems

Neophyte therapists may "play the behaviorist" and overemphasize a peripheral aspect of behavioral techniques in a way that distorts and obscures the treatment. We have seen sensitive clinicians become brusque and coldly demanding as they assume their fantasied role of a behaviorist. This tendency may result partly from the emphasis on technique at the expense of subtler interpersonal issues in the behavior therapy literature. The neophyte behavior therapist may also be highly invested in learning a new technique and, as a result, may consciously dispense with the "old" (i.e., knowledge of the commonsense principles of psychotherapy) in order to concentrate on learning the new.

Systematic desensitization requires that the therapist be active, directive, and quite specific in his expectations of the patient. Some therapists have difficulty making these demands because of prior training, experience, or personal characteristics. In some cases the therapist can become more comfortable about making these demands if they are more fully understood and begin to seem as sensible as techniques like asking the patient to lie on a couch or to free associate. Since the demands are numerous and explicit in SD, difficulties surface early and present the therapist with a series of clinical decisions such as whether to confront the patient, lessen or switch the demand, or discontinue SD. Clinicians must handle these difficulties without creating unnecessary power struggles.

Another factor is the therapist's personality—some clinicians have much difficulty assuming a directive stance. When this is the major block to pursuing SD, self-appraisal on the part of the therapist may be necessary.

Patient-Related Problems

In order to conduct systematic desensitization with outpatients, the patient must provide accurate self-reports. A number of characteristics can interfere with accurate reporting. Some individuals have little interest in reducing symptoms but get strong reinforcement from the appearance of losing them or of being actively engaged in treatment (e.g., an exhibitionist under court-ordered treatment).

Difficulty with accurate self-reports may also arise when a patient fears criticism or failure, which he may see as leading to abandonment or other aversive consequences. In these circumstances, it is important to make it clear that the therapeutic contract is to help the patient with his problems and that no one technique is necessarily crucial to this function.

In SD, the patient must cooperate with a structured, directive regime. This may evoke fearful distortions around issues of control and dominance in a range of personality types, from the mildly rebellious to the extremely suspicious and paranoid. With some patients, pointing out their fear of being controlled is sufficient to elicit cooperation. If this fails, there are other options. The therapist may need to wait until a more trusting therapeutic alliance is established; unfortunately, this can lead to almost endless delays if the patient is very suspicious. An alternative that may make sense, depending on the total clinical picture, is the use of self-administered systematic desensitization (14), in which the patient retains "control" of treatment by carrying out the bulk of the therapeutic work at home, under his/her own supervision and at his/her own pace.

SD requires that the patient take responsibility for practicing certain behaviors that may be inconvenient and/or uncomfortable (e.g., confronting frightening situations in vivo) as the SD progresses. Paradoxically,

some patients request behavior therapy because they hope to magically avoid the responsibilities and discomforts necessary for behavioral change. Clarification and reduction of these expectations is usually important, since the patient who expects a magical cure often will not participate in assignments needed to ensure real behavioral change.

As with every other kind of therapeutic work, the patient must enter SD with some minimum expectation of success. Thus patients who feel that anything they do is doomed to failure will have difficulties with SD. When expectation of success is lacking because of depression or a history of failures, it is sometimes helpful to establish an initial positive experience (e.g., easy, graded, in vivo assignments) before attempting SD.

Perhaps the most difficult patient-related problem is that of the person who receives more reinforcement from retaining his symptom than anticipating its removal. This is a complex area which will be dealt with in our discussion of how systematic desensitization fits into the overall therapeutic goal and how this relationship should affect management of the therapy.

THERAPEUTIC DECISION MAKING

Often, problems encountered in treating a patient with SD are reflections of other treatment problems that the therapist thinks are worthy of pursuing. For example, a patient may be unable to relax in the office because he is paranoid and afraid of being controlled by the therapist. Although the SD is clinically important (e.g., treating a driving phobia that is interfering with the patient's job), the patient's suspiciousness may be even more serious and may distort his functioning in all life areas. One of the most important factors in deciding how to manage problems arising in SD is how the specific technique and its goal fit into the overall treatment objectives for the patient. There are three basic possibilities: 1) the total treatment goal is the resolution of the problem being treated by SD, 2) the therapist and patient agree on treatment goals that extend beyond the specific goal of SD, or 3) the therapist and patient agree that the problem being treated by SD needs therapeutic attention, but there is disagreement about the need for further treatment, with the patient usually denying that he has anything more than a focal problem.

In conditions 2 and 3 listed above, the management of therapeutic issues is complex because there are multiple treatment goals, and the priority of any goal may shift as therapy progresses. When other difficulties surface during the course of SD, it is sometimes possible to treat the original SD goal and the new problem simultaneously. Often, however, the therapist must decide whether to push on with SD or to treat some new or accentuated problem. We will present guidelines that should help therapists reach appropriate conclusions.

When and How To Pursue SD

When the goal of SD is the total therapeutic objective (i.e., condition 1 above), it is clear that the therapist should attempt to solve problems encountered in the SD in the most expedient manner possible. For example, if the patient is unable to relax in the office, this difficulty should be explored when it appears likely that discussion will lead to a rapid resolution of the problem. If such exploration seems unproductive, the therapist can employ one of several options based on his understanding of the therapist-patient-problem constellation. For example, a methohexital-aided SD (15) might be used when the patient has a strong—even magical—belief in the efficacy of medical treatment. On the other hand, the therapist might opt for self-administered SD with a patient who fears giving up control in therapy.

It is important to pursue SD when there is some urgency in relieving the patient of the target symptom. This is the case when the symptom will become much more difficult to treat in the future, i.e., when a symptom is generalizing (traumatic phobia becoming agoraphobia), being increasingly reinforced (by the acquisition of a phobic partner), or has possible severely debilitating effects (a man with a flying phobia who is about to lose a very suitable job because of his inability to travel).

SD should also be pursued when it appears that its success will place the patient in a better position to confront his other difficulties. An example would be an individual with an animal phobia that constricts his/her world and obscures serious interpersonal problems. When a phobia is masking other difficulties, SD frequently goes smoothly until treatment nears completion, at which time the patient may become increasingly apprehensive. This "end-stage anxiety" has several sources. The patient begins to enter in vivo situations that were previously avoided, and he/she also anticipates new anxiety-provoking situations. The patient's life may have centered around the symptomatic problem; as the symptom subsides, the patient may feel there is a void in his/her life and there is nothing to fill the "vacuum" created by successful treatment. Continuing with SD in spite of such anticipated difficulties may be a first step in teaching the patient to cope with his/her problems in manageable segments.

The last relative indication for pursuing SD occurs when it constitutes an important means of modeling and metacommunication for the patient. This may be particularly valuable when the patient has a chronic tendency to pursue problems briefly, dropping them before they are solved. In this situation therapeutic goal-directedness conveys the sense that the therapist has a clear understanding of therapeutic priorities and that the patient's transient fluctuations in attitude are not cause for redesigning therapy. The therapist thus models more appropriate problem-solving methods for the patient.

When and How To Defer SD

Systematic desensitization should be deferred when significant problems arise that urgently need treatment. The mechanisms by which this occurs are similar to those cited in the earlier discussion of pursuing SD (i.e., generalization, increased reinforcement, or altered consequences of the other problem).

An alternative problem that is uniquely accessible to therapy should often be pursued. This occurs, for example, when a patient being desensitized to a focal phobic difficulty suddenly becomes aware of his lonely, restricted existence, and the therapist feels the patient's usual denial will obscure his/her feelings of isolation if the issue is dealt with later.

Therapeutic objectives should be changed when a patient begins treatment with a token problem but begins to feel comfortable enough, as the therapeutic alliance is strengthened, to reveal more important difficulties. The therapist must then determine whether the token problem is real but minor (requiring later treatment) or was exaggerated as an entree into therapy.

Systematic desensitization usually must be abandoned when it appears that it will not succeed until the disruptive problem is resolved. Some patients get more reinforcement from defeating or frustrating the therapist than from successful treatment. In these cases it is usually important to examine the therapeutic relationship and the patient's feelings about the therapist rather than attempting to resolve the problem by modifying the SD or by introducing a new technique. Even if the patient cannot engage in such introspection, the therapist may help the patient realize that he is actively creating his therapeutic failures.

SD may fail when there is a great deal of reinforcement for the symptom. For example, when the patient has a phobic partner, SD is most useful when the partner (or family) is given supplemental counseling directed toward reducing the interpersonal reinforcement of the symptom (16, 17).

Even when a decision concerning the pursuit or abandonment of segments of SD is made, there is the further question of how much of this reasoning should be shared with the patient (a problem that arises in all therapies). For example, when control of some aspects of treatment is given over to a paranoid patient who distorts collaboration into dominance or submission, one can present the change to self-administered SD to the patient as an efficient way of proceeding, or one can tell the patient that closer collaboration would be desirable but that it appears difficult at this time. Again, the therapeutic decision of whether to make such a statement is in part a function of the relationship between SD and the overall treatment plan.

CONCLUSIONS

Systematic desensitization takes place within the larger framework of a therapeutic alliance, in which careful attention to interpersonal factors is crucial. We have tried to delineate pitfalls for the therapist in incorporating SD into this larger framework. Systematic desensitization, like any other therapeutic intervention, will be ineffective if interpersonal issues are oversimplified or major issues in a patient's life are ignored.

In this paper we have outlined guidelines that may help therapists make sound decisions as choice points occur during systematic desensitization. In these guidelines, the anticipated gains and losses at each decision point are not based on hard data but on clinical judgments, such as when an individual is uniquely ready to face a particular problem or whether a patient's difficulty precludes a successful course of classical desensitization. This framework, in modified form, may prove useful in the application of other behavioral techniques. Our analysis has also generated testable hypotheses (i.e., the relative success of self-administered SD with paranoid personalities) in the crucial area of the interaction of personality characteristics with the application and outcome of specific techniques.

Brief Versus Standard Hospitalization: The Families

BY MARVIN I. HERZ, M.D., JEAN ENDICOTT, PH.D., AND ROBERT L. SPITZER, M.D.

A total of 175 newly admitted inpatients who lived with families were randomly assigned to three treatment groups: standard inpatient care (discharge at the therapist's discretion), brief hospitalization (one week or less) with transitional day care available, and brief hospitalization without day care. Outpatient aftercare was offered to all patients. There was no major differential family burden as a function of length of hospitalization. Generally, brief hospitalization had several positive effects on family functioning, primarily earlier resumption of occupational roles and less financial burden, with few significant deleterious effects.

IN RECENT YEARS there has been a trend toward early discharge of hospitalized patients in order to avoid the potentially deleterious effects of prolonged hospitalization. While the evidence indicates that brief hospitalization is beneficial for most patients (1, 2), the effects on their families are less clear. Several studies (3–5) have shown that families bear some of the burden when an attempt is made to maintain patients in the community rather than in the hospital. To our knowledge there are no controlled studies comparing the effects on families of brief versus a longer term hospitalization.

This paper, the second report of the results of a controlled study of brief hospitalization, focuses on the initial results concerning the effect on the patients' families and, in addition, on the families' perception of the patients' condition. The first report (1) described the initial results regarding the outcome for the patients as evaluated by such indices as days in the community, rehospitalization rate, and measures of psychopathology and role functioning as evaluated by therapists and research interviewers. Briefly, the average length of inpatient stay until "first significant release" (1 week in the community) was 11 days for the two groups receiving brief therapy and 60 days for the group receiving standard therapy. There were no statistically significant differences in rehospitalization rates for the patients at risk. All three groups made substantial but equal improvement on all measures of psychopathology. However, at 3 and 12 weeks the standard group showed the most impairment in role functioning.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are with the New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032, where Dr. Herz is Director, Community Services, Dr. Endicott is Director, Evaluation Section, Biometrics Research Unit, and Dr. Spitzer is Chief of the Unit. At the time this work was done Dr. Endicott was Co-Director and Dr. Spitzer was Director, Evaluation Section, Biometrics Research Unit, New York State Department of Mental Hygiene, New York, N.Y.

This work was supported by Alcohol, Drug Abuse, and Mental Health Administration grant MH-19831 from the National Institute of Mental Health and by the New York State Department of Mental Hygiene.

The authors wish to acknowledge the contributions of Drs. Stephen Reibel and Kenneth Greenspan, Senior Attending Psychiatrists, Community Services, who supervised the clinical procedures, and Mses. Miriam Gibbon, Rose Bender, and Sarah Lichtenstaedter, who were responsible for the data collection.

METHOD

A total of 175 newly admitted inpatients who had families were randomly assigned to the following three treatment groups:

1. Standard-out group (N=63): standard inpatient care with discharge at the therapist's discretion.
2. Brief-day group (N=61): brief hospitalization (generally less than one week) followed by transitional day care if appropriate.
3. Brief-out group (N=51): brief hospitalization with discharge to the community.

The same therapeutic team followed the patient through all treatment modalities, and all patients were offered outpatient therapy.

The study was conducted on the Washington Heights Community Service of the New York State Psychiatric Institute. The service is responsible for a catchment area with a population of 90,000 in an ethnically diverse lower-income area of upper Manhattan. The criteria for inclusion in the study and the demographic characteristics of the patients were presented in detail in our first report (1). Essentially, the primary diagnosis had to be functional illness other than alcoholism, drug abuse, or antisocial personality. The most common diagnosis was schizophrenia (63%); approximately one-third of the subjects were black; slightly over half were in social classes IV and V (6); approximately half had had at least one previous psychiatric admission; slightly less than half were currently married; there were equal numbers of men and women; and over half of the patients were under the age of 35. The only statistically significant differences among the three groups of relevance to prognosis were

fewer married patients in the brief-out group than in either of the other groups and more men in the brief-out group than in the brief-day group.[1]

The differential effects of the three treatment programs were evaluated at admission, at 3 weeks, and at 3, 6, 12, 18, and 24 months after admission. Research interviewers used the Psychiatric Status Schedule (7) with patients and the Family Evaluation Form (8) with family informants, and therapists completed the Mental Status Examination Record (9).

FAMILY EVALUATION FORM

The data reported in this paper were obtained by research interviewers who used the Family Evaluation Form (FEF) to interview family members about patients and their families during the week prior to the evaluation. The family evaluation interviews were begun a few months after the study started. The FEF, developed by Spitzer and associates (8), consists of an interview guide and an inventory of 455 items that are grouped into 45 summary scales on the basis of content and similarity to factor analytic studies of similar scales.[2] It covers three major areas: patient evaluation, family evaluation, and family difficulties due to the patient. The FEF takes approximately 45 minutes to complete.

Patient Evaluation

Some items describe the patient's psychopathology and cover such areas as subjective distress, social isolation, and disorganization-impaired reality testing. For these areas a family member was simply asked such questions as, "Has he been anxious?" and "Does he have trouble sleeping?" Other items describe the patient's role functioning.

Family Evaluation

Almost every item asked regarding the patient was also asked concerning the family (e.g., "Has anyone else in the family been anxious?" and "Has anyone else had trouble sleeping?"), and the items were scored "true" if any member of the family was reported to have exhibited the behavior. In addition to the measures of symptoms in the family, there are other items that describe such areas as household functioning, financial problems, and special problems related to children.

Family Difficulties Due to the Patient

The third group of items concerns family difficulties that are due to the patient. There are several different types of items reflecting family burden. Whenever a family member's symptoms or impaired functioning was acknowledged, the informant was asked, "Do you think it has anything to to with [the patient's] condition or was exacerbated by [the patient's] condition or situation?" There are other items reflecting difficulties that directly involve the patient, for example, "Do people feel they have to be very careful what they say or do in order not to upset him?" "Does anyone feel embarrassed or ashamed because of him?" "How much do you worry about his getting better (or getting sick again) or how his illness will affect the family in the future?" Another group of items reflects behaviors that have face validity as objective burdens on the family, for example, "Has he hit anyone?" "Did someone have to take time off from work to be with him?" "Has he been deliberately uncooperative or stubborn?"

RESULTS

The FEF evaluation at admission revealed no significant differences among the three groups on measures of the patients' psychopathology, the families' psychopathology, or the families' difficulties due to the patient. Thus the randomization procedure was successful. To evaluate the differential effectiveness of the treatment approaches, the FEF data were compared at the item and the summary scale level for the 3-, 12-, and 24-week evaluations. Both cross-sectional analysis of variance and analysis of covariance using the initial evaluation as a covariate were performed. The results reported here are derived from the cross-sectional analysis of variance because more subjects were available for these analyses since the admission FEF was introduced several months after the study began. The results from the analysis of covariance were consistent with results reported in this paper.

DESCRIPTION OF PATIENTS

Out of 72 scale contrasts comparing patients' symptoms, there were only 2 statistically significant summary scale differences among the groups. At 3 weeks, psychomotor disturbance was slightly higher for the two brief therapy groups than for the standard therapy group. At 12 weeks, the standard group had a higher score on a scale of miscellaneous psychopathology, such as poor judgment in handling money, than did the brief-out group. Thus the reports from the families agreed for the most part with those of the therapists and research interviewers. There were essentially no differences in the levels of symptoms in the patients in the three groups for any follow-up evaluations. All groups showed considerable improvement over time.

The only significant differences regarding role functioning were the following: At the 3-week evaluation the standard group had more impairment in the wage-earner and housekeeper roles than did the brief-out group. At 12 weeks both the standard and the brief-day

[1]All references to statistically significant differences involve two-tailed t tests with $p<.05$.

[2]A table presenting these summary scales, the number of items in each, and their interclass correlation coefficients of reliability is available from the authors on request.

groups showed more impairment in wage-earner functioning than did the brief-out group. The finding that the brief-out patients more quickly resumed their wage-earner role is in part explained by the larger number of patients in this group who were back in the community full time at both evaluation points. Even by 12 weeks, almost one-third of the standard group was still in the hospital and almost one-third of the brief-day group was still attending day care.

DESCRIPTION OF FAMILIES

There were no significant differences in the 7 summary scales of psychopathology of family members at 3, 12, or 24 weeks for the three groups. Regarding family functioning, at 3 weeks the families of both brief groups had more impairment in household functioning than did those of the standard group. This difference was largely accounted for by items reflecting unpleasantness at mealtimes and disagreements over handling money. There were no differences in any of the measures of family functioning at 12 or 24 weeks.

Family Difficulties Due to the Patient

The only statistically significant differences in measures of family difficulties attributable to the patient's condition or situation, out of 117 contrasts, were at 3 weeks. The brief-day group had a higher score on the summary scale of community problems due to patient than did the brief-out group; the brief-out group had a higher score on the scales of objective burden due to patient and psychiatric treatment due to patient than did the standard group. The difference in objective burden was primarily accounted for by items reflecting the patient's uncooperativeness and interference and the family's statement that other adults and children in the family were "neglected because of the patient."

At the end of the interview, the rater completed the following single 5-point global item: "Taking everything into consideration, how much of a burden do you think this patient has been on his family during this week?" The mean level for the three groups was not statistically significantly different at any of the evaluations, although at 3 weeks both brief groups showed more ratings in the "moderate" and "severe" categories. Thus the data seem to indicate that there were few differences among the groups and that those differences which were found were at 3 weeks.

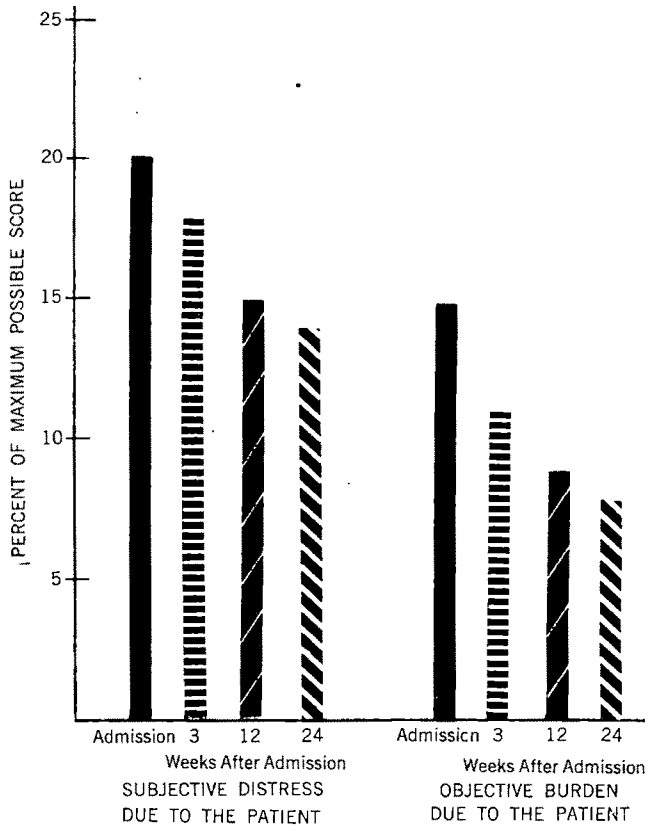
It is important to realize that over 90% of all brief-therapy patients were sleeping at home at that time and had been there an average of 16 days, while over half of the standard patients were still full-time inpatients and those sleeping at home had been there an average of only 6 days.

Frequently Reported Family Problems

What kinds of family difficulties attributed to the patient's condition or situation were reported at 3 weeks, *regardless of treatment group membership* (since there were no major differences between the groups)? Table 1 presents items that were either commonly reported (by more than 20% of the families) or that describe problems frequently mentioned in the literature on family burden. The results are presented for the total group and, to determine any differential effects due to the location of the patients, for the families of the 100 patients who were at home and the 53 patients still hospitalized. (Since the family evaluation interviews were begun a few months after the study started, the first 22 patients did not have the initial FEF interview.)

Almost two-thirds of the families reported worrying about the future because of the patient's illness. Other common problems included various manifestations of subjective distress, such as trouble sleeping, nervousness, having to be careful not to upset the patient, and worrying about financial problems. Few families reported being embarrassed or ashamed, and none were afraid of being harmed by the patient.

The most common items having to do with objective burden reflected the patients' failure to contribute as much financial support as would be expected, the families' having to assume responsibilities that had been the patients', and being inconvenienced because of the amount of time spent with the patient or doing things for him. Specific patient behaviors that have face validity for indicating burden, such as being noisy at night or deliberately uncooperative, were of low frequency. The most frequent was the report that the patient was irritable or angry (16%). It is of great interest that there were few differences in the frequency of items reflecting burden as a function of whether the patient was in the community or in the hospital, and none was significant. Family members reported symptoms such as insomnia and nervousness whether the patient was at home or in the hospital.



Evaluating all of the families together regardless of treatment group, were there changes over time in family difficulties attributed to the patient's condition or situation? There were only two summary scales reflecting family difficulties on which there was sufficient magnitude on admission for there to be detectable change over time (figure 1). These were subjective distress in family members attributed to the patient's condition and objective burden due to the patient. At each successive follow-up evaluation, the scores on both scales showed considerable improvement in both measurements. This agrees with the interviewers' global rating of overall family burden, which declined from 32% of families with a "moderate" or "severe" burden at 3 weeks to 21% at 24 weeks. Examination of specific items shows a similar downward trend, with the difficulties previously noted as most commonly reported at 3 weeks still most common at 24 weeks, for example, "worry about the future" (62% to 47%), "nervous, tense, afraid" (37% to 26%), "have to be careful not to upset the patient" (35% to 24%), "trouble sleeping" (20% to 16%), "had to assume patient's responsibilities" (38% to 19%).

TABLE 1
Percent of Family Respondents Reporting Family Difficulties Due to the Patient at 3 Weeks*

Item	Total (N=153)**	Patients at Home (N=100)	Patients Still Hospitalized (N=53)
Subjective distress in one or more family members due to the patient			
Worry about the future	62	62	62
Nervous, tense, afraid	37	35	40
Have to be careful not to upset patient	35	37	30
Sad, depressed	25	26	25
Trouble sleeping	20	19	22
Worrying about financial problems	20	16	28
Feel embarrassed or ashamed	7	9	4
Afraid of being harmed by patient	0	0	0
Objective burden due to the patient			
Patient contributes less money than if well	42	39	47
Family had to assume patient's responsibilities	38	37	40
Family is inconvenienced because of amount of time having to spend with patient or doing things for him	21	22	19
Patient is irritable or angry	16	19	12
Patient is afraid to be alone	14	18	6
Family missed work	14	9	4
Some adult in family is neglected	10	14	4
Patient is deliberately uncooperative	9	11	6
Patient makes demands on family	9	10	8
Patient is noisy at night	8	11	4
Patient interferes with the activities of others	7	9	2
Patient gets into arguments	3	5	0
Patient gets into fights	2	2	2
Patient needs help with everything (dressing, etc.)	2	1	4

* Scaled items were considered present if rated as moderate or above.
** Since the family evaluation interviews were begun a few months after the study started, the first 22 patients did not have the initial FEF interview.

FIGURE 1
Changes in Measures of Family Burden

Effects on Children

Slightly over one-third of the families had a child of 18 years or younger living at home. In one-half of these families the patient was the parent, and in the other half the patient was an older sibling or some other relative. Since the number of families with children is small, the results are reported as trends that are not statistically significant. At 3 weeks the level of disturbance or problems in all the children was small. The most common disturbance was in the area of subjective distress. One-fifth of the families reported having one or more children who were either quite a bit or extremely "unhappy or upset." The frequencies of all other items ranged from 0 to 10%.

Disturbances in children were rarely attributed to the patient's condition, with the exception of subjective distress: approximately three-fourths of the informants who reported an unhappy or upset child attributed it in some way to the patient's condition. It is noteworthy that this attribution was made whether the patient was at home or in the hospital. However, for a few of the other items, which were rarely reported (average=7%), such as the child being hyperactive, disobedient, or angry due to the patient, the patient was invariably living at home.

At the time of the 3- and 24-week evaluations, how were the patients who had children and were living at home functioning as parents (N=27 and 35, respectively)? We have only the interviewer's global judgment of parental role performance after asking the family informant questions about parental role functioning. At 3 weeks 69% of the parents were judged "good" or "very good" in performance of this role, while 22% were rated "poor" or "very poor." By 24 weeks 86% were rated "good" or "very good," and 11% were rated "poor" or "very poor."

TABLE 2
Correlation of Patient Psychopathology with Measures of Family Burden at Admission and 3 Weeks

Patient Psychopathology	Family Subjective Distress Due to the Patient		Family Objective Burden Due to the Patient		Interviewer's Judgment of Family Burden	
	Admission R	3 weeks R	Admission R	3 weeks R	Admission R	3 weeks R
Subjective distress	.34	.33	.28	.67	.33	.56

Patient's occupational role functioning	.16	.24	.34	.36	.24	.40

Relationship Between Patient Psychopathology and Family Burden

Which types of patient psychopathology had the greatest relationship to family burden on admission and at 3 weeks? Table 2 shows the intercorrelation between the different summary scales of patient psychopathology and the three major summary measures of family burden (family subjective distress due to the patient, family objective burden due to the patient, and interviewer's judgment of family burden). As expected, such patient behaviors as belligerence, unpleasantness, disorganization, and those which reflect impaired reality testing had the highest correlation with measures of family burden. The generally higher correlation at 3 weeks than at admission is partially accounted for by the greater variability among the patients at 3 weeks, since on admission most patients were moderately to severely ill while at 3 weeks some were in remission while others remained severely ill.

Family Attitude Toward Treatment Program

What was the attitude of the families in the different groups toward the treatment programs? Although none of the differences was statistically significant, some interesting trends are suggested. It is of note that at 3 weeks twice as many of the informants in the standard and brief-day groups as in the brief-out group judged that the patient, who was now at home, had come home too soon. This finding is remarkable since most of the standard patients were home because the therapists thought they were ready, whereas many of the brief-out patients were home only because the therapists were conforming, somewhat reluctantly, with the study protocol. The difference between the brief-day and brief-out groups is equally puzzling since the expectation was that the availability of transitional day care would lessen the burden on the family. By the 24-week evaluation there were no real differences among the groups, but slightly over one-fourth of all families still believed that the patient had come home too soon.

Regarding the item, "Should the patient be back in the hospital?," at 3 weeks 30% of the brief-day families answered in the affirmative compared with 13% of the brief-out and 16% of the standard families. By 24 weeks about twice as many of the standard informants (21%) as brief informants (11% brief-day, 9% brief-out) thought the patient should be back in the hospital, suggesting that the longer initial hospitalization produced more family intolerance.

The informants' attitudes were generally positive toward the treatment staff. Only the standard group showed a decline in a positive attitude from the 3rd to the 24th week (82% to 66%), whereas both brief groups showed a trend in the opposite direction.

DISCUSSION

In this paper we have attempted to compare the initial differential effects on patients' families of brief hospitalization (average 11 days), with or without transitional day care, with standard hospitalization (average 60 days), with discharge at the therapist's discretion. All patients were offered outpatient aftercare. The overall finding of the study is that there were very few statistically significant differences on any of the measures among the three treatment groups in spite of numerous contrasts made. In the discussion that follows, the reader should keep in mind that some of these differences could have occurred by chance and that the results are based on interviews of family informants rather than on direct observations of family functioning.

The Patients

Generally, the family informants' reports of patient psychopathology agreed with the ratings of research interviewers who examined patients directly and with the ratings made by the patients' therapists, which were reported previously (1). Initially, there were no

significant differences in psychopathology among the groups, and only a few small differences were found at 3, 12, and 24 weeks after admission. Since family members had more opportunity to interact with and observe the patients in both brief therapy groups at 3 weeks (when over 90% of them were home, while most standard patients were still hospitalized), it might have been expected that patients in the brief groups would have been described as "sicker." On the other hand, patients in the brief groups might have been considered less sick by family members because hospital staff influenced their judgment by stating that the patient was no longer in need of hospitalization. Even if this attitude existed, it is unlikely to have affected the FEF scores because the specificity of the items reduced the possibility of any "halo effect."

Informants' reports of patient role function indicated that the brief-out patients were less impaired in the wage-earner role than were the standard patients at 3 weeks and both the standard and brief-day patients at 12 weeks. This is probably related to a lack of opportunity to work while on inpatient or day-patient status, loss of job because of prolonged absence, or a lack of motivation to work (regression with lowered self-esteem and self-confidence).

The Families

The intergroup differences in family psychopathology, family functioning, and subjective and objective burden were minimal in all cases. The only differences occurred at 3 weeks, when some of the brief-out patients exhibited unpleasantness, uncooperativeness, and negativism. This finding was not unexpected since many of the brief patients were still in the process of resolution of their acute psychotic episodes. The major positive effect of brief hospitalization on the families was the greater likelihood that brief-out patients would return to work and contribute financially, thus lessening family financial worries. This was true at each of the follow-up evaluations.

The research interviewers' global evaluation of family burden tended to confirm the finding that brief hospital treatment placed an additional burden on some families at 3 weeks. Despite this, at 3 weeks 82% of the families of brief-out patients were in favor of having the patient at home, and only 13% believed that the patient should be in the hospital.

Satisfaction with the treatment program was very high for all groups. This is probably related to the positive relationship that families developed with our active and supportive social service staff. However, it is interesting to note that by 24 weeks, 28% of family informants from all groups believed the patient came home too soon. Of further interest is the finding at 24 weeks that twice as many of the standard informants (21%) as all brief informants (10%) believed that the patient should be back in the hospital despite the longer initial hospitalization. This attitude was present even though there were no statistically significant intergroup differences on any measures of burden and not even any trends in the direction of more burden on the standard families. This included the interviewers' global evaluations, which described 20% of all families as having moderate to severe burden. Perhaps during the longer absence of the standard patients from their families family members "closed ranks," i.e., they assumed some of the patient's roles in the family, were less tolerant of deviant behaviors, and were not so ready to reintegrate the patient into the family.

What accounts for the differences between brief-day and brief-out informants' attitudes at 3 weeks regarding a feeling that the patient had come home too soon (37% for brief-day versus 18% for brief-out) and that the patient should be back in the hospital (30% for brief-day versus 13% for brief-out)? Since only about half of the patients in the brief-day group used day care, the others going directly to outpatient care, it is most likely that a chance difference in demographic characteristics of the two samples is largely responsible. The brief-day patients were significantly more likely to be women, married, and parents. It has been found that the mother's role in family functioning is most vital and difficult to substitute for (10), and this might account for a greater intolerance for an imperfectly functioning mother, especially if the informant was the husband. These demographic differences between groups may also account for the brief-day group's greater utilization of social service time in the first 3 weeks, as reported in our previous paper.

Our failure to find any major *differential* family burden as a function of length of hospitalization should not obscure the finding that there is considerable burden for many families when one member has a serious psychiatric illness. This burden is understandably greatest just prior to hospitalization but persists long after the patient has shown considerable improvement and is back in the community.

The possible deleterious effects on children of returning a seriously disturbed family member to the home while he is still in the process of recovering from an acute episode is an important consideration. Results for all groups at 3 weeks indicated that reported disturbances in children attributed to the patient's condition were rare, but when they did occur the patient was at home. In addition, most of the patients who were parents were apparently able to perform well in their parental role immediately after a brief period of hospitalization, although a small group of parents were reported to be performing very poorly and it is unknown whether a more prolonged hospitalization would have benefited their children. It might be important to monitor closely the performance of parents sent home after a brief hospitalization.

Generally, the results indicate that brief hospitalization has several positive effects on family functioning, primarily earlier resumption of occupational role functioning and less financial burden, with few significant deleterious effects. In our previous paper we concluded that brief hospitalization was generally preferable to longer hospitalization as far as the patient was

concerned, and it is evident that a similar conclusion applies for most families, at least insofar as our initial results indicate. This conclusion may only be applicable to programs that offer continuous care and that consider hospitalization as only one modality in a spectrum of treatment services.

Prognostic Correlates of Psychotherapy in Psychiatric Outpatients

BY ARTHUR K. SHAPIRO, M.D., ELMER STRUENING, PH.D., ELAINE SHAPIRO, PH.D., AND HARVEY BARTEN, M.D.

The authors examined the follow-up data for 113 psychiatric outpatients who had been treated for up to a year in an outpatient community mental health center. Correlations between therapist and patient ratings of improvement were generally low, and analyses were done separately for therapist and patient ratings. The strongest confirmed hypothesis was the relationship between therapist and patient ratings of improvement and therapist and patient evaluations of each other as likable, physically attractive, and either a good patient for treatment or a competent therapist. The authors discuss the advantages and disadvantages of multivariate statistics for the analysis of psychotherapy data.

STUDIES OF PSYCHOTHERAPY have accumulated in the literature, resulting in several comprehensive reviews (1–4). These reviews have emphasized the need for further data about the correlates of clinical course, prediction of improvement, relationship between ratings of improvement by the patient and therapist, relationship of the placebo effect to improvement, relationship between positive feelings of the patient and therapist toward each other and clinical course, and the application of multivariate procedures to the data of such studies.

Our purposes in this study were to test specific hypotheses derived from the literature and from a previous study (5), to relate characteristics of patients and therapists to clinical course, and to develop meaningful hypotheses for subsequent study. This work was stimulated by our continued interest in the placebo effect, patient-therapist attraction, and other variables in treatment. It was in part an attempt to replicate a previous study of the placebo effect (5), in which clinical improvement was positively associated with a quantified measure of reaction to a placebo test and negatively associated with chronicity and intensity of symptoms. As a result of our previous work (6–11) we became interested in placebo test variables and the attitudes of the patient and therapist toward each other as important variables in therapy.

The hypotheses involved several sets of variables that were expected to predict clinical course. We hypothesized that improvement during treatment would correlate positively with reaction to placebo and patient-therapist attractiveness and negatively with chronicity of illness and severity of symptoms.

METHOD

The initial group of subjects for this study were 113 patients who consecutively applied for treatment at a community mental health clinic in Westchester, N.Y., who fulfilled the usual outpatient criteria: age between 17 and 65; 6 or more years of education; capable of completing forms and following instructions; not referred by a court or legal agency; not diagnosed as organic, senile, addicted, or alcoholic; not in psychiatric treatment during the past 6 months; not previously in treatment at the clinic; and in treatment at the clinic for at least one visit. Patients were evaluated by the clinic director within 1 week of their application and assigned to appropriate therapy with 1 of 13 therapists, who varied in sex, discipline, experience, and treatment orientation. The patients were evaluated for follow-up status up to 1 year after the initial evaluation. Patients were informed that they were participating in a study of the therapeutic process.

DEPENDENT VARIABLES

Our dependent variables consisted of ratings of clinical course by patients and by therapists on a 7-point scale that ranged from marked worsening to marked improvement. Follow-up status was evaluated for four different groups of patients according to how long they remained in treatment: patients in treatment for 1–3

Dr. Arthur Shapiro is Clinical Professor of Psychiatry and Director and Dr. Elaine Shapiro is Clinical Assistant Professor of Psychology in Psychiatry, Special Studies Laboratory, Payne Whitney Clinic, New York Hospital-Cornell University Medical College, 525 East 68th St., New York, N.Y. 10021. Dr. Struening is Associate Professor and Director, Epidemiology of Mental Disorders Research Unit, New York State Psychiatric Institute, Columbia University, New York, N.Y., and Dr. Barten is Clinical Associate Professor, Cornell University Medical College, and Director, New Rochelle Guidance Center, New Rochelle, N.Y.

The analysis of data for this report was supported in part by Alcohol, Drug Abuse, and Mental Health Administration General Research Support grant MH-14706 from the National Institute of Mental Health, by the Titzell Teaching Fund, Cornell University Medical College, and by Hoffmann-La Roche, Nutley, N.J.

The authors wish to express their appreciation to the psychiatrists, psychologists, and social workers who provided the therapy and evaluations and to other staff at the Mount Vernon Mental Health Clinic, Westchester Community Mental Health Board, Westchester, N.Y., and to Ann Rosen, M.A., and Gerald K. Raab, M.A., who helped with the statistical analyses.

months (N=28), 4–6 months (N=25), 7–12 months (N=34), and patients still in treatment after 12 months (N=26). A final set of dependent variables consisted of the patient and therapist ratings for 97 of the patients when their therapy terminated. Follow-up data were available for about 85% of the sample of 113; about half of the unobtainable data were for patients in the group in treatment for 1–3 months.

INDEPENDENT VARIABLES

With the evaluations of clinical course described above as dependent variables, the variables described below were selected as possible predictors of clinical course, some of them according to hypotheses previously stated.

The independent variables comprised two broad groups: pretreatment variables, or data obtained before treatment began, and concurrent-with-treatment variables, or data obtained during therapy.

Pretreatment Variables

Six subgroups of variables made up the pretreatment group: demographic, history of illness, diagnostic, symptom, MMPI (including the authoritarian scale), and our placebo test scores.

The demographic variables included age, sex, race, religiosity, social class, ethnic background, national background, sibling rank, number of siblings, and marital status. Our rating of religiosity was based on the patient's belief in a personal God and the frequency of his or her religious observance. The mean age of the patients was 32, and their mean social class was 4.1 (12). Seventy-three percent of the patients were women, 58% were white, 89% were Catholic or Protestant, and 21% were single.

The history of illness variables included age at onset of illness, duration of current episode, duration of present illness, previous psychiatric treatment, and previous psychiatric hospitalization. The mean age at onset of illness was 28 years, and mean duration of current episode was 8.7 months. Thirty-five of the patients had had previous psychiatric treatment, and 12% had been hospitalized previously.

The diagnostic variables included the diagnoses of neurosis, psychosis, personality disorder, anxiety, and depression. These diagnoses were based on the initial impression of the clinic director. The phi coefficients between initial diagnosis and diagnosis after treatment varied between .79 and .88. Sixty-five percent of the patients were diagnosed as neurotic, 10% as psychotic, and 25% as having a personality disorder.

The symptom variables were derived from a 47-item symptom checklist developed by Parloff and associates (13) and Frank and associates (14) and modified by Williams and associates (15). The factor scales used in this study were general neurotic feelings, somatization, and fear-anxiety. Clinical clusters were depression, obsessiveness, withdrawal, paranoia, feelings of unreality, and total score.

The MMPI variables included the 13 standard scales as well as the following experimental scales (16); ego strength, anxiety factor, repression factor, dependency, dominance, social desirability, acquiescence (17), sum true (16, 18, 19), inhibition of hostility, and Taylor manifest anxiety. The authoritarian scale (20) was included with the experimental MMPI scales because it did not fit elsewhere.

The placebo test variables have been described in greater detail elsewhere (21, 22). These were derived from the patient's responses to placebo rated on a 7-point scale that ranged from maximum worsening to complete relief of symptoms during the hour following ingestion of a placebo tablet. Responses were categorized as positive placebo effect (39 patients), negative placebo effect (20 patients), or neutral response to the placebo (39 patients). A final group consisted of 15 patients who refused to take the placebo test.

Concurrent-with-Treatment Variables

The variables obtained during therapy included four subgroups: therapist, length and type of treatment, type of termination of therapy, and patient-therapist attractiveness.

The therapist variables consisted of the sex and professional status of the therapist. Of the 8 female and 5 male therapists, 5 were psychiatrists, 5 were social workers, and 3 were psychologists.

The type of treatment variables comprised individual treatment (90 patients) and combined individual and group therapy (23 patients). About half of the patients in each group also received drug therapy.

The length of treatment variables included number of therapy sessions (mean=16.1), months of treatment (mean=6.7), and sessions per month (mean=2.1). The length and intensity of treatment in this study compared favorably with the length of treatment reported by Garfield (23), who found that about 67% of 560 patients seen at a Veterans Administration clinic came for fewer than 10 interviews.

The variable of type of termination of therapy included mutual termination of treatment (39% of the patients), dropping out of treatment (35%), and remaining in treatment after 12 months (20%). Six percent of the patients had moved, died, or could not be located at the time of follow-up.

The patient-therapist attractiveness variables were obtained at 3, 6, and 12 months, and when therapy terminated, on a 7-point scale that rated the patient's and therapist's evaluation of each other as likable, physically attractive, and a good patient for treatment or a competent therapist. These variables were examined during the course of therapy at each evaluation period.

DATA ANALYSIS

The tests of association used to test our hypotheses included the phi coefficient, chi-square test, and prod-

TABLE 1
Correlations Between Therapist and Patient Ratings of Improvement

Patient Group	Time of Evaluation	Correlation	Significance*
Patients in treatment for 1–3 months (N=15)	1–3 months	r=−.39	n.s.
Patients in treatment for 4–6 months (N=22)	1–3 months	r=.05	n.s.
	4–6 months	r=.02	n.s.
Patients in treatment for 7–12 months (N=58)	1–3 months	r=.26	p<.05
	4–6 months	r=.43	p<.001
	More than 7 months	r=.44	p<.001
Patients rated at completion of therapy (N=90)	Completion of therapy	r=.29	p<.01

* By two-tailed t test.

uct-moment correlation coefficient.

The dependent variables were the ratings of improvement by the patient and the therapist. As shown in table 1, the correlations between the ratings of the patient's improvement by the patient and the therapist were generally low: negative for patients in treatment for 1–3 months, uncorrelated for patients in treatment for 4–6 months, moderately correlated for patients in treatment for 7–12 months, and weakly correlated for all patients rated at termination of therapy. These low correlations were unexpected and led to an interest in understanding the different criteria used by therapists and patients in judging clinical course. Low correlations between patient and therapist ratings have been reported elsewhere (4, 24).

To identify variables associated with various measures of placebo reaction, 73 independent variables were categorized into the 10 groups described above. Subsequently, independent variables were introduced within each group in a stepwise multiple regression analysis until the last variable selected did not account for a sufficient amount of dependent variable variance to be significant at the 5% level. The purposes of this analysis were to select the variables most highly associated with the evaluation of clinical course by patients and therapists, to eliminate those contributing redundant variance, and to identify those accounting for unique variance in the dependent variables.

In a summary regression analysis, the variables selected from each of the 10 groups were submitted to stepwise analysis to make a final selection of variables accounting for significant and unique variance in clinical course variables. Only two summary regression analyses will be presented in this paper.

RESULTS

Table 2 summarizes the significant correlations between 73 independent or predictor variables and for each of the two dependent variables. Since there were 20 significant correlations for the therapist ratings of improvement and 31 for the patient ratings of improvement, more significant correlations were obtained for each of the dependent variables than the 7.3 expected by chance at the .10 level of significance.

HYPOTHESES

The predictions about positive placebo reactions and improvement were not supported, although trends in that direction were found.

An unexpected finding occurred for the patients who refused to take the placebo test. Refusing was negatively correlated with the therapist's rating of improvement, but refusing was not related to the patient's rating. The correlation between refusing to take the placebo test and therapist rating of improvement at 4–6 months was −.33 ($p<.10$); at termination of therapy for all patients it was −.20 ($p<.05$).

The hypothesis that chronicity of illness would be negatively related to improvement was consistently but modestly supported by the therapist's, but not by the patient's, rating of improvement. The correlation between therapist rating of improvement and duration of current episode was −.20 ($p<.05$); the correlation between therapist rating and duration of present illness was −.21 ($p<.05$).

The hypothesis that the patient's report of severity of symptoms before treatment would correlate negatively with clinical course was strongly supported according to the patient's rating, as indicated in table 2. This relationship was also apparent in the MMPI scores for patient but not for therapist ratings.

The hypothesis that the patient's evaluations of the therapist as likable, physically attractive, and competent would positively correlate with each other and with the therapist's rating of improvement was confirmed, as indicated in table 3. Similarly, the hypothesis about the therapist's evaluation of the patient was confirmed. Intercorrelations of the three varied between .46 ($p<.001$) and .63 ($p<.001$). The multiple correlation coefficients for likable, attractive, and good or competent with improvement were .56 for the therapist ($p<.001$) and .51 for the patient ($p<.001$). The hypothesis that patient and therapist attitudes would correlate with each other was not confirmed.

The possibility that the patient's evaluation of the therapist was an objective judgment of his or her likableness, physical attractiveness, or competence was evaluated by obtaining the ratings of therapists about each other on the same variables. There was no relationship between the judgments of the patient and therapist on these variables.

Another way of illustrating the relationship between patient's and therapist's liking each other and improvement is shown in figure 1. The percent of patients rated improved by patient and therapist was related to their scores on likability for the four periods of evaluation during therapy (see figure 1) and the evaluation period

at termination of therapy. If patient and therapist liked each other, their respective ratings of improvement varied between 77% and 96%. However, if the therapist did not like the patient, the improvement reported by the therapist varied between 52% and 62%. Of even more importance, if patients did not like their therapists, only 21% to 25% reported themselves improved at 1–6 months, and none reported improvement at 7–12

TABLE 3
Intercorrelations of Patient Ratings (N=95) and Therapist Ratings (N=97) of Improvement, Likability, and Attractiveness or Competence at Completion of Therapy

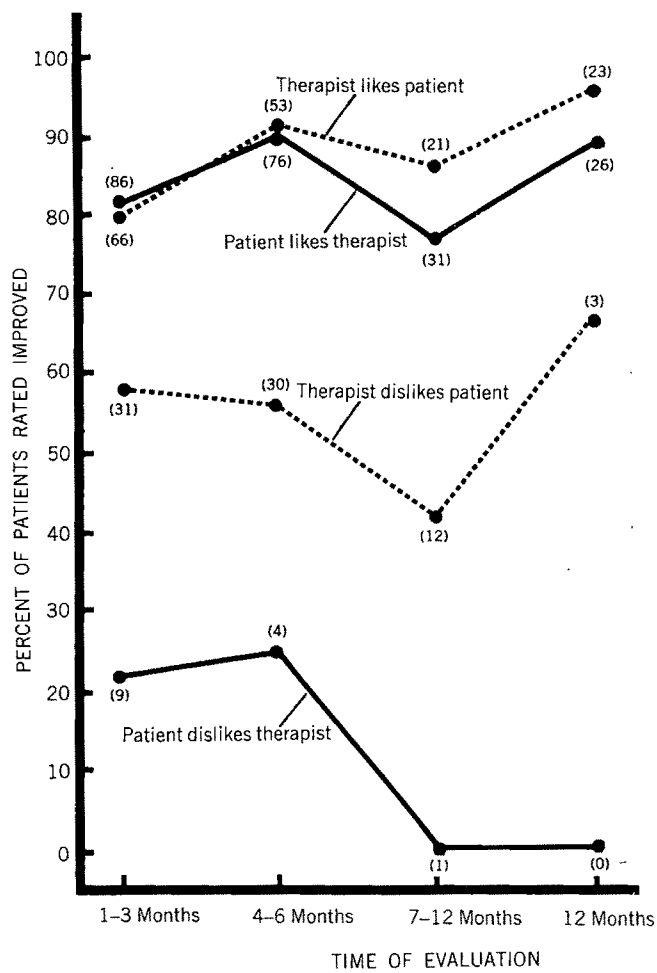
months. Finally, in the group of patients evaluated at completion of therapy, only 4 of the patients did not rate their therapists as likable; all 4 of these patients reported themselves unimproved.

Multiple Regression Analyses



The multiple regression hypothesis was that there would be a predictive relationship for the placebo test, history of illness, symptom, patient-therapist attractiveness, and clinical course variables.

For the variable of patient's rating of improvement, 4 pretreatment and 3 concurrent-with-treatment variables were selected from 73 original variables by stepwise multiple regression analyses (see table 4). The multiple correlation coefficients were .52 for the 4 pretreatment variables and .56 for the 3 concurrent-with-treatment variables. When all independent variables were combined, the multiple correlation coefficient was .63, indicating that about 40% of the variance could be attributed to these variables. Significant, unique, and independent variance was contributed by the variables of competent and physically attractive therapist, mutual termination, and low initial MMPI scores for psychopathic deviate and anxiety factor.

For the variable of therapist's evaluation of improvement, 3 pretreatment and 2 concurrent-with-treatment variables were selected (see table 4). The multiple correlation coefficients were .44 for pretreatment variables and .57 for concurrent-with-treatment variables. When all of the independent variables were combined, the multiple correlation coefficient was .66, indicating that about 44% of the variance in improvement could be attributed to these variables. Significant, unique, and independent variance was contributed by the variables of good patient for treatment, low MMPI score for psychopathic deviate, taking the placebo test, and short duration of illness.

These results indicate partial support for the hypotheses selecting the most efficient set of variables for pre-

FIGURE 1

dicting clinical course, although the exact combination was not anticipated.

CONCLUSIONS

The following tentative conclusions can be derived from this preliminary study. Both patients and therapists rated patients described as psychopathic deviates on the MMPI as less likely to improve in therapy, a conclusion consistent with clinical experience. Positive evaluations of each other by both patient and therapist were related to their respective ratings of improvement but were uncorrelated with each others' positive evaluations and ratings of improvement. Whether the likability, attractiveness, and good/competent variables were antecedents, concomitants, or consequences of improvement cannot be specified by our findings. Patients rated themselves improved if they terminated treatment with mutual consent of the therapist and if they had low initial complaints of anxiety. Therapists rated chronic patients and those who refused to take a drug test as not improving in psychotherapy.

COMMENT

For studies of psychotherapy that include many variables, multiple regression can help select variables that make significant contributions and, further, identify variables that account for significant and unique variance in the dependent variables.

Shortcomings of the procedure are that large samples and sophisticated techniques, including assessment of reliability, data reduction with factor analysis, and computer facilities, are necessary for analysis of the data. The results from multiple regression procedures tend to be unstable, especially if large numbers of variables are examined; replication is therefore essential. Considering the large number of variables examined, there is, of course, the possibility that the relationships

reported in this paper were due to chance. The contributions and shortcomings of this study can best be identified through replication with increased attention to sampling, conceptual, and measurement issues. Such studies are in progress.

The Murdered Child and His Killers

BY DAVID KAPLUN, M.S.W., AND ROBERT REICH, M.D.

The authors studied 112 cases of child homicide in New York City in 1968–1969 to identify contributing social and psychiatric factors and to determine the fate of the surviving siblings and the degree of involvement of the city's social agencies with the families. There was a pattern of long-term familial child maltreatment extending to the siblings and continuing after the murders. The victims were usually illegitimate preschoolers; the assailants, usually the mothers or their paramours, had backgrounds of assaultiveness and social deviance and killed in impulsive rage. Reports of sexual abuse of victims or of suicide or psychosis among assailants were rare. The authors present case illustrations and offer guidelines for improved prevention by psychiatrists and social workers.

EACH WEEK, municipal statistics tell us, at least one of New York City's children is murdered. The number of such killings has steadily mounted, particularly in the 1–4 age group. For this group homicides more than doubled between 1965 and 1969 compared with the previous 5 years. These figures do not take into account the deaths listed as accidental, which outnumber homicides by four to one, although review of some of these "accidental" deaths indicates that the possibility of homicidal assault cannot be excluded.

In 1968–1969, 140 apparent homicides of children under the age of 15 were reported in New York City, according to the records of the city's Chief Medical Examiner. Of these victims, 28 could not be identified. We reviewed the postmortem reports and the results of preliminary police inquiries on the remaining 112 victims. In 66 cases the victims' families were known to the city's public assistance and child welfare agencies, and we reviewed all available case reports on these families.

This report will describe the information gathered from these records on the murdered children and their siblings, parents, and assailants in an effort to determine the psychiatric and social factors contributing to the deaths of the children and to the subsequent fate of the survivors. We will review the part played by the city's mental health, child welfare, and law enforcement agencies and will consider the outlook for early identification of high-risk cases.

THE VICTIMS

Boys outnumbered girls by 15% in the population we studied, and in the case of children over the age of 10 there were 2 boys for every girl. The majority of the children (52%) were under a year old, and another 26% were between the ages of 1 and 5.

Most of the families of the murdered children (70%) lived in areas of severe poverty, and almost all were known to the city's public welfare agency. Other authors (1, 2) have similarly reported the high incidence of child abuse cases in impoverished areas. Two-thirds of the victims from public welfare families were either the youngest children in their families or had no siblings. Two-thirds of the victims were born out of wedlock: of the 13 victims without siblings, 12 were illegitimate. Simons and associates (3) also reported high figures for illegitimate child abuse victims. The proportion of homicide victims who were illegitimate was substantially higher than the 50% illegitimacy rate that has been reported for children of New York City families on public assistance generally (4). Finally, in nine-tenths of the cases reviewed, the victims, their siblings, or both had been physically abused or neglected before the killings. A report showed that in half of 34 abuse cases in Washington, D.C., parents abused each other or siblings of the reported abused child (5).

The case of Juan A illustrates the history of a child who was abused before the homicidal assault.

Case 1. Mrs. A was 17 when she and Mr. A married, a month after she had become pregnant with her son, Juan. After 2 years her husband, whom she described as an abusive alcoholic, left her 4 months pregnant and in need of public assistance. Mrs. A's caseworker saw her as a sweet-tempered, affectionate young woman overburdened with home responsibilities. The little boy seemed happy, bright, and friendly. Mr. A made unexpected home visits, having been told by his mother that his wife had an addicted paramour. On one such visit there was a quarrel in the course of which Mrs. A slashed her husband with a kitchen knife. She spent a night in jail on his complaint.

A week later Mrs. A brought Juan, now 3, to a nearby hospital (one of the finest teaching institutions in the city) with bruises, burns, and a leg fracture, caused, she said, by a fall

from a crib against a hot radiator. During the hospitalization the child was asked about this, and said that Mommy had beaten him and burned his heels with a cigarette. Because of Mrs. A's constant visits to the hospital, with home-cooked food, the hospital concluded that the father, who visited separately, had coached the child to make false statements, and Mrs. A was allowed to take him home. Psychiatric evaluation was considered unnecessary because the public assistance caseworker concurred in this view. Eight months later the child was brought back with a swollen eye, attributed by Mrs. A to a boiler explosion in the home.

Four months later Juan was murdered. Mrs. A first stated that the massive injuries, which the postmortem report said were the result of blunt force, were caused by a convulsion the child had on a mattress with a broken spring. When a police investigation disclosed that the mattress was in good condition, Mrs. A said that her 18-year-old addicted paramour, by whom she was pregnant, had done the killing during her absence from the apartment. The young man, who had a criminal history, was released after passing a lie detector test. The two surviving siblings were taken from Mrs. A. Social workers observed that Mrs. A showed "inappropriately flat affect" when discussing the killing and that she arranged a costly funeral.

THE ASSAILANTS

Over two-thirds of the assailants in the cases we studied were parents or paramours. The most frequently named assailant was the mother, a finding that agrees with results of a study on child abuse (6). The mother usually acted alone but sometimes acted with her paramour. The biological father was the killer in only 10% of the murders, and minor siblings or other children were almost never implicated. The older the victim, the less frequently was his murderer a parent. While babies were killed by parents 83% of the time, the figure for preschoolers was 53%, that for schoolchildren under 10 was 30%, and that for those over 10 was 17%. Paramours rarely murdered their own children; instead they killed the sons of their predecessors. Except in the cases in which children were under 2 years of age, assailants and victims tended to be of the same sex. This was true in 31 (73.6%) of the 42 public welfare and other cases in which there was information on both the age and sex of the victim and the sex of his reported assailant. (Application of the Clopper-Pearson confidence coefficient formula for a binomial distribution indicates a 90% probability that the percentage would be between 61.4% and 83.3%.)

In 81% of the public welfare cases in which information was provided on the assailants, the assailants showed prehomicidal deviant behavior, mostly alcoholism, narcotics use, and criminal involvement. Diagnosed psychoses were rare, and suicide attempts were even rarer. Posthomicidal suicide attempts occurred in only 4% of the cases. This finding is contrary to some reports in the European literature (7, 8) but is similar to other American findings (9).

In 13 cases the mothers were not the killers but gave access and opportunity to the assailants and tried to protect them from being apprehended. In such cases the men, usually paramours, had criminal or assaultive histories, while the mothers were generally known as gentle and loving.

In 20% of the cases the mother was pregnant at the time of the murder; in another 9% she had a newborn child. In only 2% of the cases did the postmortem examination show that the assailant had sexually molested his victim. Finally, the means employed in the killings, mainly beating and kicking, were suggestive of impulsive rage rather than premeditation.

THE VICTIMS' FAMILIES

The families of the victims differed from the New York State public welfare family caseload described by Storfer (4) in at least three important respects: 1) the children in the homicide families less frequently all had the same biological parents (39% versus 63%); 2) the homicide families had more children under the age of 3 (73% versus 35%); and 3) the homicide families had many more teenage mothers (25% versus 2%).

Studies of the families of abused children have shown frequent severe marital discord (10). This was true of the families we studied. Of 35 cases in which there were legal or consensual marriages, 33 cases showed separations, divorces, or assaults, and in 71% of the cases the mothers had multiple short-term extramarital relationships.

In addition to child maltreatment and marital discord, all but 9.2% of the families we studied showed evidence of other behaviors prior to the assault that would be considered socially or psychiatrically deviant. These behaviors and their incidences are indicated in table 1. This evidence of a high prevalence of deviant behavior is paralleled in several studies of

TABLE 1
Type and Percentage of Deviant Behaviors Reported Among 61 Public Welfare Families of Child Homicide Victims Before the Homicides

Behavior	Percent of Families
Narcotics addiction or dependency	33.6
Alcoholism	29.7
Assaultiveness (other than child abuse)	27.9
Adult crime (excluding prostitution)	27.9
Juvenile crime	14.8
Mental retardation	13.1
Undiagnosed psychiatric condition	11.5
Psychosis	11.5
Prostitution	9.8
Juvenile conduct problems	8.2
Suicide attempts	8.2
Habitual association with criminals	6.6
Epilepsy	3.3
Other behavior requiring outpatient psychiatric care	1.6
No deviant behavior (other than child abuse) reported	9.2

child abuse and homicide both in the United States (11–13) and in New Zealand (14).

The case of Mr. and Mrs. B illustrates the role of deviant behavior and also the lack of public recognition of psychopathological factors in setting the stage for child murder and its aftermath.

Case 2. Young Mr. and Mrs. B had three sons, aged 3, 2, and 8 months. They were frequently separated during their 3-year marriage. Mr. B was a violent alcoholic, had a history of criminal activity in his teens, and continued associations with criminal friends during his long periods of unemployment. He and his wife, also an alcoholic, fought frequently. On one occasion, Mrs. B hit her husband on the head with such force that stitches were required. Both parents beat and neglected the children. The youngest died of bruises, head injuries, and malnutrition. Although the death was listed as a homicide, Mr. B's explanation that it was accidental was later accepted for lack of objective evidence to the contrary. Another child, born shortly afterward, died after 5 days, reportedly of a collapsed lung.

The parents were later brought to court on charges of neglect and abuse of their 3-year-old, who had been struck with a pot thrown by his mother at 4:00 a.m. on her return from a local bar. She had meant to strike her husband, not the child. The court, unaware of the previous deaths, did not request a psychiatric evaluation and dismissed the abuse charge, since the injury did not appear to have been deliberate. The child was placed with another relative, but the other surviving son remained in parental custody. Following this, neighborhood complaints of the parents' drunkenness, promiscuity, and child abuse continued. Psychiatric evaluation was planned but was not carried out.

In one-fifth of the cases, the victim or a sibling had been placed in an institution or foster home because of parental problems. In five of the nine cases in which the victim himself had been in such care, the killing occurred either in the foster home or during a trial discharge to the parents. The case of Victor C illustrates this pattern:

Case 3. Miss C, a soft-spoken and ladylike person, had her first out-of-wedlock child, a girl, when she was 16. Following the birth she continued living with her mother, to whom she seemed attached. When she became pregnant again at 17, she asked that the coming child be placed so she could go to business school. This was done. In the next year Miss C did not once visit the baby, Victor, but continued relationships with men, one of whom beat her so badly that her mother called the police. Miss C made such a good impression on the foster-home social worker that she arranged a trial discharge of Victor to Miss C and her mother. A few weeks later two teen-age boys whom Miss C often entertained in her apartment entered it in her absence and found the baby brutally beaten. They brought him to a hospital, where he died. The 2-year-old girl seemed unharmed.

It turned out that the child was murdered by Miss C's latest paramour, Mr. M, a drug addict with a prison record and a period in a mental hospital. When he was arrested he attempted suicide. Miss C tried to protect Mr. M first by saying that the baby had choked on food and then by saying that an aunt of Mr. M's had done the killing and that he was the finest man she had ever known. She discussed Victor's death "entirely without affect." Shortly after the murder Miss C's mother found her in bed with a girl. Both were under the influence of drugs—not the first time her involvement with narcotics had come to the agency's attention. Miss C verbalized an interest in psychiatric help at this point but broke all appointments that were made for her.

THE PROBLEM OF CONTINUING JEOPARDY

After a child has been murdered there are generally surviving siblings or subsequently born children. In 79% of the cases we studied in which children remained in parental custody following the homicide, there was evidence of possible jeopardy, and in 32%, continued neglect or abuse was a matter of record. The case of Mr. and Mrs. B illustrated such jeopardy. In a similar case no charge was pressed against the father, a violent criminal who used narcotics, after one death because the evidence was deemed insufficient for court purposes. In this case a younger child later died under suspicious circumstances, and another sustained a subdural hematoma and multiple fractures. In the latter instance the hospital physician refused to file a child-abuse complaint although he was aware of earlier injuries because he was impressed with the mother's gentle manner and did not know about either her own past episodes of ungovernable violence or the husband's history.

PSYCHIATRIC, SOCIAL SERVICE, AND LAW ENFORCEMENT INVOLVEMENT

Table 2 shows the amount of involvement of the city's many mental health, social service, and correctional agencies, excluding the public welfare department, with the public welfare families before and after the murders.

When penal and correctional institutions were excluded, we found that before the murders 61% of the public welfare families were known to social or mental health agencies and that 47% were known to such agencies afterward. In both periods, the contact with psychiatric, counseling, and guidance agencies was negligible.

Law enforcement activity, as shown by review of 60 of the public welfare cases, was meager and minimal. In 20 cases, no suspect was arrested. Of 25 cases in which postarrest information was available, 17 suspects went to trial. Virtually all alleged assailants were given short sentences on reduced charges in return for guilty pleas, and one case was dismissed because the witness to the killing was a 10-year-old sibling whose testimony was deemed inadmissible on the ground of age. Only in one case—a highly publicized one in which the father had drowned his child—was there a conviction for first-degree murder. Psychiatric evaluation was used only in the cases of four women who were sent to state hospitals.

TABLE 2
Involvement of Community Social Agencies and Institutions with Victims' Families Before and After the Murders

Type of Agency or Institution	Percent of Cases Known Before the Murders (N=59)	Percent of Cases Known After the Murders (N=57)
Correctional or penal (excluding pretrial incarceration)	13.5	21.1
Institutional or foster care for children	27.1	15.8
Inpatient psychiatric facility (including institutions for retarded)	13.5	13.9
Outpatient psychiatric service	10.2	5.3
Narcotics service	5.1	5.3
Child protective service (voluntary agency)	11.9	3.5*
Child guidance service in schools	16.9	1.8*
Family counseling (voluntary agencies)	6.8	0
Child guidance (other than school)	8.5	0

*These figures come from study of the 46 cases in which there were children who remained in the parents' care after the homicides.

DISCUSSION

The murder of a child is the final chapter in his history of maltreatment. That history develops against a background of poverty and violence. There is usually pervasive psychopathology in his family—assaultiveness, criminality, alcohol and drug abuse, and, more rarely, frank psychosis. Equally pervasive are marital discord and sexual promiscuity. The dead child, usually illegitimate, is the victim of the parental hostility that triggers the homicidal assault. That assault is unpremeditated and impulsive, and similar ones directed against siblings or spouses occur before and after the killings.

Only rarely are the violence-prone adults associated with these homicides recognized by their community agencies as needing psychiatric attention, and they do not seek such attention on their own. What, then, are the prospects for early identification of children in potential jeopardy? Such identification cannot be made with certainty. But bearing in mind that the great majority of the cases came from poverty-saturated areas and that most were known to the public welfare agency, it would seem that professionals who serve young mothers with out-of-wedlock children in such areas should identify cases in which some of the following six questions have affirmative answers:

1. Does an adult in the home have a history of assaultiveness toward children *or* adults, of involvement with crime, drugs, or alcohol, or of episodes of impulsive rage?
2. Is there an unwanted pregnancy, with a neglected or abused child already in the home?
3. Where there is a legal or consensual marriage, is it marked by discord and physical violence?
4. Is casual promiscuity or prostitution the mother's way of life?
5. When children are seriously ill or badly injured, has there been failure or delay in seeking or using available medical care?
6. Are relationships with neighbors or relatives characterized by mutual hostility or avoidance?

Further research with suitable control groups should be attempted to determine whether such questions would effectively differentiate child abusers from nonabusers. In addition, psychiatrically oriented studies should be done of the manipulative mother who does not herself do violence to her child but who creates opportunities for others to do so and whose verbal expressions of maternal solicitude are contradicted by objective observation of the treatment the child receives at her hands.

Our study throws into question the widely held belief (15) that the abused child is the family scapegoat, battered by his parents while his siblings are unharmed. We have repeatedly seen the contrary. Our study also does not tend to support the belief that severely abusing parents are receptive to counseling or psychotherapy: the extreme, long-standing psychopathology, the host of coexisting problems, and the paucity of insight and motivation all tend to point against this view for most cases.

The responsibility of the psychiatrist working in child welfare settings or in the courts should be to provide diagnosis and guidance based on examination, thorough case record review, and knowledge of the realities of ghetto life. Psychiatrists who serve as consultants to foster-care agencies or who testify in courts should see to it that psychiatrically significant criteria are correctly used in foster-parent selection, that proposed returns of children to previously abusing parents are carefully evaluated, and that psychiatric factors in abuse cases are adequately presented in court.

Journal Policy on Multiple Authorship

It has come to our attention that there has been some misunderstanding regarding the *Journal*'s policy on polyauthorship. The number of authors listed on a paper is not a factor in the review and acceptance/rejection procedure. However, once a decision has been made to publish a paper, we do apply *Journal* policy regarding the number of authors in the by-line: only principal researchers and writers of articles are listed in the by-line; collaborators who have provided technical and other assistance are acknowledged in a footnote. In papers that list more than 4 people as principal authors, we query the first author to verify that those individuals were substantial contributors to the research or ideas reported. Since certain types of psychiatric research may require multiple workers, we will of course include all of the names in these cases.

l-Alpha-Acetylmethadol (LAAM): Prognostic Considerations

BY RICHARD B. RESNICK, M.D., LOIS ORLIN, M.S.W., GRETCHEN GEYER, ELAINE SCHUYTEN-RESNICK, M.S.W., RICHARD S. KESTENBAUM, PH.D., AND ALFRED M. FREEDMAN, M.D.

The authors studied the responses of 28 adult male volunteers who were openly changed from methadone to l-alpha-acetylmethadol (LAAM) maintenance. They found that patients who had been receiving middle-range doses (50–70 mg) of methadone required a significantly lower mean increase in LAAM than patients who had been receiving either high or low methadone doses and that the patients who accepted LAAM differed significantly from those who did not in MMPI 2-point-code ratings and mean social adjustment scale scores. These findings may provide prognostic indicators for response to LAAM, a possible alternative to methadone.

THE LITERATURE REPORTS that *l*-alpha-acetylmethadol (LAAM) may be an effective alternative to methadone in narcotic substitution therapy. A congener of methadone (1–3), LAAM suppresses abstinence for up to 72 hours and may be administered three times a week, which can satisfy the therapeutic aim of having patients visit clinics less often without adding to the public health problem of diverted methadone. While participating in a 40-week cooperative open-label study of the safety and efficacy of LAAM sponsored by the Special Action Office for Drug Abuse Prevention (SAODAP), we examined nonpharmacological factors that correlated with success in treatment.

In 1952 Fraser and Isbell (4) reported that a single 60-mg oral dose of LAAM alleviated abstinence from morphine for 72 hours in man. In a small double-blind pilot study that corroborated this finding, Jaffe and associates (5) found no significant differences in social adjustment between patients maintained on daily methadone and those maintained on *d*, *l*-alpha-acetylmethadol administered three times a week. In subsequent clinical trials at the Illinois Drug Abuse Program, Chicago, and at New York Medical College, both blind and open studies found comparable ratings of improvement in patients treated with LAAM and those treated with methadone (6–9). These studies also further defined the duration of opiate activity at different doses.

METHOD

Sixty adult male volunteers participated in the study. Inclusion criteria were a history of 2 years' addiction, a minimum of 1 month of methadone maintenance before entering the study, absence of serious medical problems or psychopathology, and signing an informed consent. Baseline and periodic evaluations for all of the patients included EKG, EEG, the Hopkins Symptom Check List-90 (SCL-90), SMA 12/60 (Technikon), urinalysis, and physical, psychiatric, and neurological examinations. An evaluation of psychosocial status was made for all of the patients at baseline. Sixteen of the patients completed MMPIs. Each patient was assigned to a primary therapist for counseling and social services.

Patients were randomly assigned to LAAM or to continue methadone. Patients assigned to LAAM were encouraged to continue on it but were told they could switch back to methadone at any time during the study. LAAM was administered at the clinic 3 days a week (Monday, Wednesday, and Friday), and no take-home medication was permitted. Patients receiving methadone attended the clinic 3 to 6 days a week, in accordance with Food and Drug Administration (FDA) regulations, and received take-home doses for the intervening days.

Pre-study methadone doses ranged from 20–100 mg a day. Twenty-eight patients were assigned to LAAM, which was always started on a Monday at a 1:1 cross-over dose. After the first week, LAAM doses were ad-

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

This investigation was supported by Alcohol, Drug Abuse, and Mental Health Administration research grant DA-3A732 from the Special Action Office for Drug Abuse Prevention, National Institute on Drug Abuse, Rockville, Md., and by contract C-77738 from the New York State Drug Abuse Control Commission, Albany, N.Y.

The authors wish to express their appreciation to Marcel Harris and Mary Cooper, R.N., for their aid in obtaining much of the data and to Ted Lonergan, M.D., for his medical care of the patients.

The patients' MMPIs were processed through the courtesy of Roche Psychiatric Service Institute, Inc., Nutley, N.J.

justed for the patient's comfort to a maximum of 100 mg. Assessments of the patients' symptoms and psychosocial functioning were recorded weekly during the first 8 weeks of the study and then monthly. Levels of statistical significance were determined by t tests unless otherwise noted.

RESULTS

Of the 28 patients assigned to LAAM, 20 found it an acceptable or preferable form of treatment (group 1) and 8 reported persistent physical and/or emotional discomfort that led them to return to methadone before the end of the 40-week study (group 2).

Doses

The mean starting dose for group 1 patients was 62.8 mg (range: 20–100 mg). For group 2 patients the mean starting dose was 67.5 mg (range: 30–100 mg). At 3 months' maintenance or termination, whichever occurred first, the mean dose for group 1 was 67.8 mg (50–100 mg) on Mondays and Wednesdays and 81.5 mg (60–110 mg) on Fridays. For group 2 the mean doses were 68.8 mg (30–100 mg) on Mondays and Wednesdays and 80 mg (40–100 mg) on Fridays. These differences were not significant ($p>.10$).

Because direct comparisons of doses showed no differences between groups, we evaluated dose adjustments. All 28 of the patients had problems adjusting to LAAM. All but 1 complained of withdrawal-like symptoms (insomnia, yawning, tearing), usually beginning 48–72 hours after taking the medication. In most instances these complaints were relieved by increasing the Friday dose. Two patients who started at 100 mg of LAAM had their Monday and Wednesday doses decreased by 10 mg and 15 mg; their 100-mg doses were maintained on Fridays. Fifty percent of the patients (14 of 28) requested and received dose increases on Mondays and Wednesdays. Overall, both groups received similar increments.

Comparison of the dose adjustments according to pre-study doses of methadone showed that patients receiving middle-range doses of methadone (50–70 mg) required the fewest and smallest adjustments in their LAAM doses (see table 1). Those who crossed over at lower doses (40 mg or less) required the largest increments, 25–35 mg on Mondays and Wednesdays and 35–50 mg on Fridays. We excluded 6 patients from these calculations: 2 whose 100-mg dose precluded the increases they desired and 4 who terminated in less than 3 weeks—before an optimal, stable dose could be found.

Patients who crossed over at middle-range doses received dose adjustments whose mean differed significantly from the mean dose increment of those who crossed over at lower and higher doses ($p<.01$ and $p<.10$, respectively). The differences were even more significant for the 9 patients in group 1 who had been receiving middle-range doses. None of these patients required an increase on Monday or Wednesday, and 1 required a 10-mg decrease. The 3 middle-range patients in group 2, who were raised 5 mg, 10 mg, and 20 mg, accounted for the mean increase of 1.3 mg (see table 1).

TABLE 1
Adjustments of LAAM Doses Required by 22 Patients Who Crossed Over from Low-, Middle-, or High-Range Doses of Methadone

Item	Range of Methadone Dose Before Crossover (mg)		
	20–40 (N=3)	50–70 (N=12)	75–80 (N=7)
Mean initial LAAM dose (mg)	33.3	57.9	78.6
Mean increase in LAAM dose, Monday and Wednesday (mg)	20.0	1.3	7.1
Mean increase in LAAM dose, Friday (mg)	33.3	15.0	29.3
Mean crossover ratio, Monday and Wednesday	1:1.6	1:1.0	1:1.1
Mean methadone to LAAM ratio, Friday	1:2.0	1:1.3	1:1.4
Range of maintenance LAAM dose, Monday and Wednesday (mg)	50–55	50–70	80–90
Range of maintenance LAAM dose, Friday (mg)	65–70	60–100	90–100

One patient reported severe symptoms suggestive of overdose 4–5 hours after an initial dose of 65 mg of LAAM. These symptoms lasted for 8–12 hours. The patient suffered intense anxiety as a result of this episode. With considerable staff support, however, he continued in the study for an additional 9 days so that we could try to assess the pharmacological and psychological components of his unusual reaction. He agreed to come to the clinic every day and to take LAAM or methadone blindly, but he made it clear that he would discontinue LAAM when we had completed our evaluation. The pharmacist disguised the color and taste of both LAAM and methadone. The patient then received four doses of LAAM (50 mg, 50 mg, 25 mg, and 35 mg) and, on the alternating days, five doses of methadone or placebo (placebo, placebo, 50 mg, 50 mg, and 15 mg). His symptoms abated, and he was unable to distinguish LAAM, methadone, or placebo days.

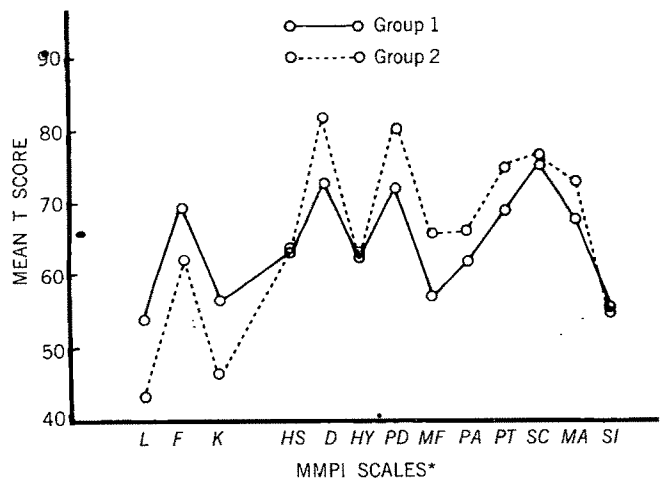
The apparent and significant ease with which patients crossed over from methadone to LAAM at middle-range doses did not, however, provide a firm basis for prognosis because several patients receiving lower and higher pre-study doses of methadone were also well satisfied after dose adjustments. We therefore explored nonpharmacological variables that might prove more useful in predicting outcome.

Background Information

Among the demographic variables of age, education, race, number of months in methadone maintenance, and number of years of opiate addiction, only years of opiate addiction differed significantly between

TABLE 2
Distribution of Number of Years Addicted Among 20 Patients Who Accepted LAAM (Group 1) and 8 Who Did Not (Group 2)

Number of Years Addicted	Group 1		Group 2	
	Number	Percent	Number	Percent
2–6	10	50.0	7	87.5
7–11	6	30.0	1	12.5
12–20	4	20.0	0	—



groups 1 and 2 ($p<.05$). In group 1 the mean was 7.9 years (range, 2–21), and in group 2 it was 4.5 years (range, 3–8). The number of years of addiction, when distributed into ranges of 2–6, 7–11, and 12–20 years, showed a trend for group 2 to have a shorter addiction history; this trend was not statistically significant (see table 2).

MMPI Scores

Eleven of the 20 patients in group 1 and 5 of the 8 patients in group 2 completed the MMPI. The patients in group 2 tended to show more deviant profiles than those in group 1 (see figure 1). In comparing clinical and validity scales for the two groups, the largest differences were in the mean scores for depression and psychopathic deviate, although none of these differences was statistically significant.

Each patient was rated on his two most elevated scales using a 2-point code (10). The 2-point code for 5 patients in group 2 included the depression, psychopathic deviate, and schizophrenia scales. Eight patients in group 1 had 2-point codes that included all of the clinical scales except paranoia and social participation; the other 3 patients in group 1 had the same 2-point codes as those in group 2. This difference in the 2-point code ratings between the acceptor and nonacceptor groups was statistically significant ($\chi^2=4.65$, $p<.05$).

FIGURE 1
Mean MMPI Scores of 11 Patients Who Accepted LAAM (Group 1) and 5 Who Did Not (Group 2)

*L=lie; F=validity; K=attitude; Hs=hypochondriasis; D=depression; Hy=hysteria; Pd=psychopathic deviate; Mf=masculinity-femininity; Pa=paranoia; Pt=psychasthenia; Sc=schizophrenia; Ma=hypomania; and Si=social participation.

Social Adjustment

Our impressions of the two groups suggested that the patients in group 1 had better psychosocial adjustments than those in group 2, so we rated each patient on a five-item social adjustment scale, using the following categories: employment, illegal activity, drug abuse, familial relationship, and treatment involvement. Each patient was rated as zero or plus for each of these items.

A plus rating for employment was given only for a verified, full-time salaried job or school attendance. A plus rating for illegal activity was given only if the patient was not known to be engaged in illegal activity for profit. A plus rating for drug abuse was given only if the patient met two criteria: he did not frequently (two or more times a week) appear to be high when seen at the clinic (on the basis of staff consensus, irrespective of what substance he used), and he denied using any illicit opioid drug (this had to be corroborated by urinalysis). A plus rating for familial relationship was given only if the patient was living with his spouse or a member of his primary family and the spouse or relative was not abusing drugs. A plus rating for treatment involvement was given only if the patient asserted that he trusted his counselor and that he found the weekly contacts to be helpful.

Group 1 social adjustment scores (mean, 3.75) were significantly higher than scores for group 2 (mean, 1.37) ($p<.01$). Eighteen of the 20 patients in group 1 had a general score of 3–5, compared with 7 of 8 patients in group 2 who had scores of 0–2. This distribution of the scores between the two groups was also significant ($\chi_2=12.38$, $p<.01$).

Patients who acknowledged their use of illicit drugs to their counselors were not given a zero rating for drug abuse unless they were using illicit opiates or were abusing drugs to the extent that they usually appeared high. Of the 11 patients who were assigned a zero rating for drug abuse, 9 acknowledged the substances they were abusing, which included heroin, methadone, barbiturates, diazepam, propoxyphene, amitriptyline, and alcohol, and 2 denied abusing drugs (except for marijuana).

The 11 patients who were rated plus for familial relationship were living with their common-law or legal wives, their siblings, or their parents. Five married patients (all in group 2) received zero ratings, 4 because their wives were known to be opiate abusers and 1 because he claimed that his wife did not know he was opiate dependent or in a treatment program.

Each of the five items of the social adjustment scale was analyzed separately. Absence of illegal activity had the highest individual correlation with acceptance

of LAAM (.73); drug abuse was second (.62) ($p<.01$). The multiple correlation between these two variables and acceptance of LAAM was .74. The other three items—treatment involvement, familial relationship, and employment—were not significantly correlated with LAAM acceptance. The multiple correlation between the combined ratings of illegal activity and drug abuse and the combined ratings of the other three items with LAAM acceptance was .73.

Terminations

All of the patients in group 2 terminated from the study, 4 within 3 weeks and 4 between 14 and 31 weeks. Those who remained in the study longer had vague, intermittent, nonspecific complaints throughout; they attributed these to LAAM. Four patients in group 1 were terminated from LAAM: 2 for medical reasons unrelated to the medication and 2 after their arrest on warrants several years old.

DISCUSSION

Dosage and Side Effects

The range of doses in our LAAM patients (50–100 mg) corresponds to those reported in other studies. Our mean dose adjustment on Friday of 1.3 mg of LAAM for every 1 mg of methadone is identical to the conversion ratio required in a study in which LAAM was blindly substituted on weekends for 40–70 mg of methadone daily (7).

The pharmacological basis for side effects and acceptability to patients is always difficult to evaluate when medication is changed openly and without controls. In double-blind studies in which LAAM was compared with methadone, no differences were observed or reported in either subjective experiences or acceptability to patients (5–7). Three of us (L.O., G.G., and E.S-R.) were involved as counselors and evaluators in an earlier study at this facility in which LAAM was openly administered to detoxified heroin addicts (8). Both low doses (40–50 mg) and high doses (80 mg) of LAAM given three times a week were well tolerated for 6 months of treatment, and evaluations of the patients receiving LAAM were equivalent to those of a control group receiving 100 mg of methadone a day in terms of patient acceptance and withdrawal symptoms, although minor side effects were more prevalent in the LAAM group.

In our current study, the results suggest that difficulties adjusting to LAAM were not due to specific pharmacological actions. Initially, most of the patients expressed apprehension that the medication might not "hold" them. For many of the patients, these anxieties were relieved after starting LAAM. Two chronically complaining patients received LAAM blind with placebo methadone on alternate days. In both cases their complaints subsided. Our evaluation of the patients whose anxieties were not relieved concurs with the impression of Jaffe and associates (6, 7), who suggested that anxiety reactions are largely psychogenic in origin and that the patient's attitude is more powerful than drug differences.

The impression that nonacceptance of LAAM is a primarily psychogenic reaction is consistent with our previous experience with 10 hospitalized patients, detoxified from opiates, who volunteered to try a "new" form of methadone called "Fioridol," which was, in fact, red-colored methadone (11). All 10 patients reported a range of symptoms (sweating, nausea, headaches, sleeplessness, anxiety) that were not unlike the chronic complaints of our patients in group 2. The patients attributed these symptoms to the medication. Because this study was open and completely supported by the staff, it is unlikely that the patients' reactions were influenced by staff attitude. When "Fioridol" was discontinued and patients were told they were getting regular methadone, their symptoms disappeared.

MMPI Considerations

The profile of mean scores of our LAAM patients matches profiles described by other investigators for populations of opiate addicts (12–15) and includes the elevated depression and psychopathic deviate scores reported to be significant MMPI differentiators of addict and nonaddict populations (13).

The patients in group 2 showed more deviant scores on 6 of the 10 clinical scales, although this difference was not statistically significant. A similar tendency in MMPI scores toward more severe psychopathology has been reported to differentiate successful from unsuccessful methadone maintenance patients (14). Group 2 patients also had abnormally low lie and attitude scores, which can indicate exaggeration of emotional problems and create an impression of serious emotional disturbance (15). Von Felsinger and associates (16) related atypical reactions to drugs to degree of emotional disturbance. The trend of the 8 patients in group 2 toward more psychopathology may have affected their reactions to LAAM.

Our finding that the 2-point code significantly differentiated nonacceptors of LAAM suggests that there may be a group of addicts whose high scores on the depression, psychopathic deviate, and schizophrenia scales of the MMPI may be useful as a prognostic index.

Social Adjustment

Our hypothesis that patients' psychosocial adjustment played a role in their acceptance of LAAM is consistent with patterns found by other investigators. In Babst and associates' study of 679 methadone maintenance patients (17), dropouts were more involved in illegal activity and more likely to be multidrug or alcohol abusers, unemployed, and unmarried. Similarly, Williams and Johnston's study of 300 methadone patients (18) found that fewer years of addiction, less involvement with drugs, and being married were positively correlated with treatment program retention rates. Resnick and associates (19, 20) found that

patients who benefited from treatment with cyclazocine were best differentiated from those who did not by having an ongoing, consistent heterosexual relationship.

The one nonaccepting patient in our study who had a high social adjustment score warrants clinical comment. When this patient began methadone treatment 4 years ago, he experienced the same adjustment difficulty as he did with LAAM (i.e., complaints of "not feeling myself," anxiety, and withdrawal-like symptoms). He continued in treatment despite his discomfort because no alternative medication was available. Eventually his symptoms disappeared. This patient has a typical obsessive-compulsive personality with somatic preoccupation. Characteristically, he reacts with somatic symptoms to any deviation from what he is accustomed to but blames his discomfort on his medication. Environmental changes may contribute to placebo reactions (21) and further explain this patient's response. We believe that this patient would have adjusted satisfactorily if no other treatment choice had been available.

Terminations

Throughout the study, we observed that staff concern and support were critical in retaining patients receiving LAAM, particularly during the early stages. Patients who responded to staff support adjusted more easily to the new medication. We believe these patients tolerated some initial discomfort because they trusted our assertions that they would feel better. This response is consistent with the role of positive transference to a therapist in counteracting negative placebo reactions (22). It is also consistent with greater psychosocial adjustment.

Three of the 4 "quick" terminators in group 2 had no treatment relationship with their therapists, but 3 of the 4 who terminated later had positive therapist relationships. These late terminators chronically complained about the medication. In our opinion, they would not have been retained for so long without positive therapeutic relationships. In other work with patients in treatment for opiate dependence, we have found that good rapport and positive transference to a therapist means a greater likelihood of remaining in treatment (23).

Implications for Treatment

In addition to assuaging the public health problems created by methadone diversion (24–26), LAAM maintenance may benefit patients by decreasing their preoccupation with medication. For example, 1 of the patients in this study stated, "For the first time in 10 years, I woke up and did not have to reach for methadone or go and get something to make me feel normal. I felt like a human being." Other patients saw the change to LAAM as an opportunity to lessen their dependence on methadone and as a useful transition toward their eventual goal of being drug free. Some viewed LAAM as a medication distinct from methadone, which they felt was only a legal fix. Patients preoccupied with their daily methadone, on the other hand, may experience deprivation from LAAM's delayed and more gradual action. We have observed that such patients frequently have limited involvement outside the drug culture and often desire opiate effects from their methadone.

Should the SAODAP cooperative studies show that LAAM is comparable to methadone in safety and efficacy and it becomes more widely available for treatment, we recommend that both drugs be administered under supervision. We believe that LAAM will be more appealing and acceptable to patients if their choice is limited to either LAAM three times a week or daily clinic attendance for methadone.

BRIEF COMMUNICATIONS

Penfluridol in the Treatment of Newly Admitted Schizophrenic Patients in a Brief Therapy Unit

BY GUY CHOUINARD, M.D., M.SC., AND LAWRENCE ANNABLE, B.SC., DIP. STAT.

The authors compared penfluridol, a long-acting neuroleptic that can be administered orally once a week, with chlorpromazine in the treatment of 33 newly admitted schizophrenic patients in a brief therapy unit. Patients receiving either drug improved enough to be discharged in 3 weeks. Penfluridol-treated patients experienced less drowsiness than those treated with chlorpromazine, but the severity of extrapyramidal symptoms appeared to be greater with penfluridol.

LONG-ACTING NEUROLEPTIC DRUGS constitute a major advance in the treatment of schizophrenic patients because they can reduce the total amount of antipsychotic drug prescribed, minimize absorption variability, and overcome the major problem of noncompliance. Penfluridol, a diphenylbutylpiperidine, chemically designated as 4-(4-chloro-α,α,α-trifluoro-m-tolyl)-1-(4,4-bis(p-fluorophenyl)butyl)-4-piperidinol, is the first neuroleptic introduced that can be administered orally once a week. Penfluridol was found by Gallant and associates (1) to be superior to placebo in the treatment of chronic schizophrenic patients, confirming results from earlier European studies. The present study was designed to compare penfluridol with chlorpromazine in the treatment of newly admitted schizophrenic patients in a brief therapy unit.

Presented at the 25th annual meeting of the Canadian Psychiatric Association, Banff, Alberta, Canada, September 24–26, 1975.

METHOD

A total of 33 newly admitted schizophrenic patients who satisfied study criteria similar to those used in the National Institute of Mental Health–Psychopharmacology Service Center (NIMH–PSC) collaborative study (2) were selected from the Allan Memorial Institute Brief Therapy Unit for inclusion in the study. Patients entered the study as they became available at the brief therapy unit, where they were admitted for a 3-week period and then discharged. All patients needed admission, and none had received long-acting neuroleptics for at least 2 weeks before the study. A 10-week follow-up of these patients will be reported in a later paper.

The patients were assigned to one of two evaluating psychiatrists in such a way that each psychiatrist evaluated a group that included both male and female patients, permitting the examination of a possible sex effect. Individuals in each group were randomly assigned to one of the two drug treatments, penfluridol or chlorpromazine, which were administered under double-blind conditions. The penfluridol dose schedule was a single dose of 40 mg the first week, 80 mg the second week, and 120 mg the third week. The chlorpromazine schedule was 300 mg a day during the first week, 600 mg a day the second week, and 900 mg a day during the third week. It was necessary to reduce the dosage for only 1 patient during the study. This patient, who was receiving chlorpromazine, had the dosage reduced after 10 days of treatment.

Of the 33 patients initially included in the study, 4 patients, all in the chlorpromazine group, were dropped and excluded from statistical analysis because they did not remain in the study for a sufficient length of time. Three of these patients developed systemic allergic reactions with edema and dermatitis,

TABLE 1
Allocation of 29 Patients to Penfluridol or Chlorpromazine, by Psychiatric Evaluator

Item	Penfluridol Patients (N=14)		Chlorpromazine Patients (N=15)		Total
	Men	Women	Men	Women	
Evaluator 1	4	3	4	4	15
Evaluator 2	4	3	3	4	14

and the fourth patient became severely agitated and could not be controlled by supplementary medication. Table 1 shows the final distribution of the 29 remaining patients to treatments. All patients, or their relatives, gave informed consent after the purpose of the study and the possible side effects were explained.

Use of supplementary medication was permitted on ethical grounds. However, it was administered only in cases of severe agitation, always followed consensus decision among the psychiatrists and nurses, and was discontinued as early as possible. Only chlorpromazine was used as adjunctive medication; it was administered by mouth in liquid form to minimize variability of absorption.

Assessment of symptoms was based on clinical interviews conducted by one of the two psychiatrists, the same psychiatrist always evaluating the same group of patients. The mental status of patients was scored before treatment and at the end of week 3 on the Inpatient Multidimensional Psychiatric Scale (IMPS) (3), the Brief Psychiatric Rating Scale (BPRS) (4), and a 7-point clinical global impression (CGI) of severity of illness. Laboratory tests and EKGs were carried out at the same time periods.

The final experimental group consisted of 29 patients, 15 men and 14 women, ranging in age from 19 to 60 years (mean 35.7, standard deviation 12.6, median 35). The mean age of the patients assigned to penfluridol treatment (34.6) did not differ significantly ($p>.05$) from that of patients assigned to chlorpromazine (36.6). Nine patients in the penfluridol group and 9 in the chlorpromazine group had a history of schizophrenia. Six penfluridol and 9 chlorpromazine patients had been hospitalized previously for short periods of time, but in no case did the total duration of previous hospitalizations exceed 1 year. Patients were classified as paranoid or nonparanoid according to the criteria of *DSM-II* (5) and as acute or chronic depending on the absence or presence of residual symptoms for at least 1 year before the current episode. Twenty-four patients (13 receiving chlorpromazine, 11 receiving penfluridol) were classified as acute, and 5 patients (2 receiving chlorpromazine, 3 receiving penfluridol) were classified as chronic. Seventeen patients (11 receiving chlorpromazine, 6 receiving penfluridol) were classified as paranoid, and 12 patients (4 receiving chlorpromazine, 8 receiving penfluridol) were classified as nonparanoid.

RESULTS

Results on each measure were subject to 2^3 factorial analysis of covariance, with drug treatment, patient's sex, and evaluating psychiatrist as factors and initial scores as covariate.[1] Table 2 lists the initial mean scores and, when appropriate, the adjusted final mean scores at week 3 on each measure. Results were considered statistically significant if they reached a .05 level of probability. Significant heterogeneity of covariate regression was limited to five measures; the unadjusted final mean scores for these measures are given in table 2. Lack of statistically significant drug × sex interaction on any measure suggests that the results are applicable to patients of either sex. Results on each measure (apart from the BPRS guilt feelings item) were also free from any of the other possible first- or second-order interactions (drug × evaluator, evaluator × sex, and drug × evaluator × sex).

Global Measures

According to scores on the CGI severity of illness scale, the total BPRS, and the total IMPS, patients receiving both treatments had highly significant reductions in psychopathology during the 3-week period ($p<.001$); all of the patients terminated the inpatient phase of the study with symptoms sufficiently reduced to enable their discharge.

The CGI severity of illness scale showed no significant difference between the adjusted mean score of patients treated with penfluridol and that of patients treated with chlorpromazine. Analysis of the BPRS and IMPS total scores indicated that the regression slope of final score on initial score for penfluridol-treated patients differed significantly from that of chlorpromazine-treated patients. Because this heterogeneity of covariate regression invalidates the use of the standard analysis of covariance based on a pooled slope, separate regression lines were fitted for the two treatments, and the range of initial scores for which there was a significant difference between the therapeutic outcomes of patients in the two treatment groups was calculated in the way Klein and Rosen calculated it (7). Further details of the statistical technique were given by Li (8).

According to both the BPRS and IMPS total scores, penfluridol was found to be significantly superior to chlorpromazine for patients with relatively low initial scores (for BPRS, initial score of 33 or less; for IMPS, initial score of 242 or less), and chlorpromazine was found to be significantly superior to penfluridol for patients with relatively high initial scores (for BPRS, initial score of 57 or more; for IMPS, initial score of

[1]Because the data contained unequal cell numbers (see table 1), analyses of covariance were carried out using a program for multiple linear regression (main effects were estimated disregarding interactions, and then interactions were estimated after adjusting for main effects) (6, pp. 441–450). In each analysis the homogeneity of the separate treatment regressions of final score on covariate was tested (6, pp. 430–436).

*Significant heterogeneity of regression. Final means are given instead of adjusted final means.
**Significant heterogeneity of regression. Final means are given instead of adjusted final means. Significant drug × evaluator interaction, attributable to unusually low variability because all patients except 2 did not have this symptom when they terminated the study.

282 or more). For patients with initial BPRS and IMPS total scores within these limits (for BPRS, between 33 and 57; for IMPS, between 242 and 282) (the majority of patients in our sample), no significant difference could be detected between the performances of the two drugs on these measures. It should be noted that the same tendency was apparent on the CGI severity of illness scale, but heterogeneity of covariate regression did not reach statistical significance on that measure.

Rating Scale Items and Factors

No significant differences could be detected between the mean outcomes of penfluridol- and chlorpromazine-treated patients on any of the individual BPRS items and factors or IMPS factors.

Supplementary Medication

Twelve of the 14 patients in the penfluridol group and 12 of the 15 patients in the chlorpromazine group required at least one dose of supplementary medication during the 3-week inpatient phase of the study. The mean daily dose of supplementary chlorpromazine received by penfluridol patients (66.0 mg) did not differ significantly from that received by chlorpromazine patients (33.7 mg).

Side Effects

Nine penfluridol patients exhibited extrapyramidal symptoms that required at least one dose of antiparkinsonian medication (procyclidine hydrochloride), compared with 8 patients in the chlorpromazine group. Among these patients the extrapyramidal symptoms were considered to be severe in 6 of the penfluridol-treated group but in only 2 of the chlorpromazine group ($p<.10$, Fisher exact probability test). However, the mean daily dose of antiparkinsonian drug received by penfluridol patients (4.1 mg) was not significantly greater than that required by chlorpromazine patients (2.9 mg). Antiparkinsonian medication was not given prophylactically, and decisions about its administration were always made by the same psychiatrist.

Moderate or severe drowsiness was experienced by significantly more patients receiving chlorpromazine (7 patients) than by patients receiving penfluridol (1 patient). There were no other significant differences among the side effects induced by the two treatments. Adverse reactions were generally mild in nature; no special measures were required for their relief. Laboratory tests (SMA-12), hematological tests, and urinalysis were all within normal limits. There were more T-wave changes with chlorpromazine than with penfluridol; this will be reported in detail in a later paper. Table 3 gives details of the incidence of side effects among the patients.

DISCUSSION

Our results appear to confirm Chien and Cole's findings (9) that long-acting antipsychotic drugs can constitute an efficacious treatment for newly admitted schizophrenic patients. The brief therapy unit was especially chosen for this study so that the relative efficacy of penfluridol could be evaluated in a short-term hospitalization setting, the main advantage of which is that the patient can be returned quickly to the community after having been stabilized by the administration of a long-acting drug.

Penfluridol appeared to differ from chlorpromazine

in its therapeutic effect in that it was less effective with patients with more acute symptoms. For the treatment of less acutely ill patients, however, penfluridol seemed to be at least as beneficial as chlorpromazine. There was some suggestion that the severity of extrapyramidal symptoms may be greater with penfluridol than with chlorpromazine, but penfluridol-treated patients experienced significantly less drowsiness than those treated with chlorpromazine.

A Favorable Response to Lithium Carbonate in a "Schizo-Affective" Father and Son

BY DAVID E. REISER, M.D., AND ALLAN BROCK WILLETT, M.D.

It has recently been suggested that patients with mania are often misdiagnosed as having schizophrenia. The authors report a favorable clinical response to lithium carbonate in a father and son with an apparent schizo-affective disorder. They conclude that some patients with schizo-affective syndromes may respond favorably to lithium but caution that a favorable response in such cases does not absolutely confirm a diagnosis of mania.

THE INTRODUCTION of lithium carbonate in the United States has stimulated a resurgence of interest in the diagnosis and treatment of affective disorders. Aside from its efficacy in the treatment of manic episodes, the use of lithium has spawned a reevaluation of current criteria for the differential diagnosis of schizophrenia and manic-depressive illness. Prior to lithium treatment, the differential diagnosis between schizophrenia and mania was of less practical importance because the two conditions were treated similarly. Widely accepted (in the United States at least) diagnostic criteria made the differential diagnosis between the two disorders seem clear cut.

The basis for distinguishing schizophrenia from mania dates back to Kraepelin (1), who emphasized that in mania, unlike in "dementia praecox," chronic deterioration did not occur. More recently an accepted authority (2) underscored the differences between the two psychoses, and other contributors (3) continue to point out these differences, emphasizing early presence of auditory hallucinations, religious ideation, delusions, impaired reality testing, ideas of reference, and later deterioration as indicators of a schizophrenic process. They underscore the importance of formal thought disorder in schizophrenia, stressing that the classic pressured speech of mania is not "loose" but linear and comprehensible.

Since the advent of lithium, however, a growing body of scientific literature has challenged these assertions. Some investigators claim that many subjects initially diagnosed as schizophrenic are later found to be manic-depressive psychotics (4–7). Taylor and Abrams (5) found that auditory hallucinations occurred in 48.1% and persecutory delusions in 42.3% of their manic subjects. Carlson and Goodwin (6) emphasized that loose associations could be documented in many manic patients, thus challenging the traditional view that true loosening of associations is pathognomonic of schizophrenia.

Other diagnostic indicators of schizophrenia are also being questioned. A study of patients diagnosed as having catatonic schizophrenia concluded that many were manic (8). Conversely, 25% of a cohort of manic-depressive patients were found to display Schneider's first-rank symptoms of schizophrenia (9).

Because of this shift in diagnostic thinking, the high familial incidence of manic-depressive psychosis, and a favorable report on the use of lithium to treat hyperactive children of lithium-responding parents, we treated with lithium carbonate a patient with apparent schizo-affective psychotic decompensation whose father had previously responded to lithium therapy (10).

CASE REPORTS

Case 1. Mr. B was born in rural Colorado in 1912, the eldest of 10 children. His father was described as quiet and even-tempered. His mother, however, was very active and "high strung and outspoken," with periods when she would "talk and talk," accompanied by bursts of intense activity. "When she got going, people half her age couldn't keep up." (Mr. B recalls no interspersed episodes of depression.) His maternal grandfather died in a state hospital following a 10-year history of grandiose efforts to make millions selling common glass stones, but there was no history of major mental illness in his 9 younger siblings.

Mr. B manifested no severe behavioral or emotional problems during childhood, but early displayed a propensity toward depression. He was highly perfectionistic and recalls being "down in the dumps for days" after "failures" such as a low grade in school. He always felt inferior to his younger siblings. During high school he continued to be sensitive to rejection and "failure." After graduation he worked as a baker and eventually owned his own shop. At 24 he married his current wife; they had 3 children in the next 8 years, and with hard work they managed well financially and socially.

When he was 44 (in 1956) Mr. B lost over $10,000 in real estate speculation. He subsequently became irritable and depressed and was hospitalized at a state hospital, where he was diagnosed as suffering from paranoid schizophrenia. He

When this paper was written Dr. Reiser was a resident, Department of Psychiatry, University of Colorado Medical Center, Denver, Colo., where he is currently an Instructor and Dr. Willett is Assistant Professor. improved after 24 ECT treatments over a 6-month period. Mr. B's wife recalled that he had changed after his mother died. He began to squander money recklessly and finally left home on a "wild spending spree" that culminated in the loss of their diligently acquired savings. After discharge he returned to construction work without any demonstrable deterioration in his thinking, object relations, or job performance.

In 1963 (age 51) he was placed on chlorpromazine (Thorazine) for irritability and temper outbursts but refused to take it regularly. Over the next year he showed extreme agitation and expressed hatred for many people. He threatened a large bakery with a suit for putting coal oil in a loaf of bread. His bickering and grandiosity increased after his father's death until his wife obtained a court order for his hospitalization. At this time (1964) he displayed a mixture of manic and schizophreniform features. He had motor hyperactivity, rapid speech, flight of ideas, his mood fluctuated from "comical and joking" to "depressed with tears," and he was angry and vulgar. Schizophreniform symptoms included loose, literal, and personalized proverb interpretations and a systematized paranoid delusion that a large bakery had deliberately poisoned his bread. He was guarded and suspicious, and had flat affect.

After treatment with phenothiazines was begun his symptoms diminished, and he was able to return to work in 5 weeks. The diagnosis was paranoid schizophrenia. Over the following year, he did not keep outpatient appointments and stopped taking his medication.

A year and one-half later (1966) Mr. B became irritable and argumentative. His distraught wife took an overdose of chlorpromazine, which Mr. B interpreted as a trick to get him into the hospital. In spite of his belief that his wife and her family were out to get him, he consented to voluntary hospitalization. During this hospitalization there were fewer manic elements; hyperactivity was not noted and pressured speech was observed only transiently. Schizophreniform symptoms were more conspicuous. While in the emergency room he insisted that there were listening devices all about. His associations were loose, religiosity was prominent, and he had marked somatic delusions. He was treated with phenothiazines and small doses of imipramine (75 mg/day) and was discharged after 5 weeks, again with a diagnosis of chronic paranoid schizophrenia. He was followed sporadically for the next 5½ years.

Shortly after the death in 1971 of a chronically ill sister, Mr. B became hyperactive, jocular, used profanity uncharacteristically, and drank excessively. He again squandered money. He was admitted again by court order with pressured speech, loose associations, and impaired abstraction of proverbs and similarities. In family meetings he showed bellicosity, flight of ideas, and hyperactivity.

A trial of lithium carbonate was then initiated. Mr. B quickly became more thoughtful, quiet, and appropriate. Family meetings were reinstituted and he returned to work. After 4 weeks in the hospital he was discharged on 900 mg of lithium carbonate per day.

He functioned stably for the next 1½ years, when lithium was stopped and he was put on low doses of chlorpromazine. During the next 3 or 4 weeks he became more expansive, insomnic, hyperactive, and grandiose; these symptoms led to a fifth hospitalization for 2 weeks in the spring of 1973. There was no evidence of a schizophrenic thought disorder during this admission and prominent manic behavior diminished when lithium carbonate treatment was reinstituted. He has remained stable since then.

Case 2. Jim B was the youngest of 3 children born to Mr. B. His older siblings have adjusted successfully to adult life. Although Jim manifested no severe behavioral or emotional disturbances during childhood, both parents noted that he was a very sensitive child who set impossibly high goals for himself, only to feel crushed when he failed. "Just like his father," his mother commented. After minor academic defeats he would be depressed for days. His object relations during childhood and adolescence were generally unremarkable, but he preferred having a few good friends to many. Jim was 12 when his father was first hospitalized. Throughout his childhood, he felt that his father cared less for him than for his other children.

Jim B completed high school with no major academic or social difficulties. However, he floundered academically on separation from home and failed out of college after one semester. A year later he "pulled together" and later completed college with good grades.

Jim B was first hospitalized at the age of 24. He was preoccupied with marital incompatibilities, which he blamed on his wife of 3 months, a recent dismissal from his first teaching job, and the threat of induction into the armed services.

He was first seen in the emergency room in September 1968, complaining of confusion, depression, and agitation. He exhibited both affective and schizophreniform clinical features. Manic elements included pressured speech and excessive talkativeness. He actively sought out relationships with both patients and staff, and the staff generally responded to him as likeable, although he demanded much attention and had a dependent quality. He was grandiose and expressed plans to write music in order to make millions of dollars and build a plush mansion devoted to music. Schizophreniform symptoms included visual and auditory hallucinations, delusions of grandeur, and the delusion that he was fused with God. He was suspicious and often felt persecuted. He also complained of feelings of unreality. The admitting resident described loose associations, and flat affect and depression were also noted. He was diagnosed as having schizophrenia, paranoid type, and started on phenothiazines. The acute psychotic symptoms remitted very rapidly and within 6 days he discharged himself from the hospital against staff advice without provisions for follow-up.

For the next 5 years Jim B worked at several fairly menial jobs, which he often lost after flare-ups with older male bosses. Although he had a "hot temper," he and his wife had many friends. She stated that Jim was well-liked, affable, easy to talk to, and "very outgoing."

His second psychotic break began precipitously in late November 1973 (age 30). He had been accepted to a high-level trainee position with a life insurance firm but was then rejected because of his prior psychiatric hospitalization. He became morose, increasingly bitter, and then sleepless and restless, with incessant pacing and moving. On December 8, 1973, he impulsively flew with his wife to Los Angeles. On the plane he was expansive and grandiose, referring to himself as a conductor of genius. When a stewardess asked him to keep his voice down he exploded angrily that he would sue her and "the whole goddamn airline." A friend who saw him in Los Angeles stated that "he kept talking so fast I couldn't keep up with him." After a day he flew home alone and came to the emergency room requesting rest and recuperation "to get my thoughts together."

One of us (D.E.R.) evaluated his mental status the morning after admission. He was disheveled and unkempt in a seclusion room and threatened to leave the hospital. His eyes had a wild expression but his affect was very flat—he dis-

played no euphoria and was emotionally remote. His body habitus was tense and guarded. Proverb interpretations were elicited; he abstracted simple proverbs fairly well, but more difficult ones evoked literal responses and loose associations.

When asked to explain his troubles, Jim drew an intricate graph of "mental balance." The graph was complex, meticulously executed, and full of cryptic detail. It resembled the typical overwrought and excessively symbolized diagrams drawn by paranoid schizophrenics. He interpreted his drawing with loose associations and a remote, emotionally flat tone of voice, although the content of the diagram dealt with emotional states. There were vectors for "too high" and "too down." The ideal place Jim B envisioned for himself was "in the middle."

He was diagnosed as a chronic schizophrenic, paranoid type, in acute exacerbation, and started on haloperidol. As hospitalization continued manic features appeared. Excessive attention-seeking, grandiosity, motor hyperactivity, and pressured speech were observed. His speech was filled with sexual themes. He offered to "buy a new hospital with the millions I'm going to make." However, frequent tearfulness, sleep and appetite disturbances, and complaints of depression were also noted. Schizophreniform features included loose associations, religiosity, paranoid trends, somatic delusions (e.g., "God has entered my body"), and hallucinations. A consultant underscored his interpersonal remoteness and flat affect and felt a formal thought process disorder was present. After a week he was less agitated and delusional, but continued to be aloof and arrogant, becoming unpredictably "loose" and excessively anxious.

He was started on lithium carbonate and haloperidol was discontinued. As soon as serum lithium levels reached therapeutic ranges he became dramatically less angry and upset. Appropriate socialization on the ward increased markedly. He found an apartment with a former friend (his wife had divorced him during the hospitalization) and a job.

Jim B is currently employed as a bus driver and has remarried. He and his wife expect their first child shortly. They have an active social life and, for the first time, he is on cordial terms with his father.

DISCUSSION

We believe that these cases corroborate recent findings that many schizophrenia-like syndromes respond favorably to lithium when there is a coexisting affective disturbance. The presence of traditionally schizophreniform symptoms does not preclude a favorable response to lithium. A therapeutic trial of lithium should be considered whenever the basic triad of manic symptoms is confounded by a schizophrenic picture.

The question of what is the most accurate diagnosis in these cases inevitably arises. Factors to be considered include the symptom picture, familial (hereditary) data, natural course of illness, and drug response.

In these two cases the family history strongly suggests transmission of an inherited mental disorder with a major manic component from generation to generation, dating back (at least) to Mr. B's great-grandfather (four generations).

The natural courses of the illnesses of these two men have both important similarities and differences. Both showed signs of narcissistic vulnerability, perfectionism, early academic disappointment, feelings of inadequacy, and job failure in young adulthood. Finally, both experienced recurrent psychotic episodes with a mixture of cognitive and affective symptoms. Both have displayed little deterioration over time, although we consider Jim B's illness too short to rule this out.

On the other hand, Jim's first episode of psychosis occurred at a much younger age (24) than his father's (age 44). Mr. B's psychoses seemed to be precipitated by deaths (object loss) and Jim's by failure (narcissistic loss). Jim B's early shyness and marital instability may suggest greater difficulty in object relations. Furthermore, his symptom picture has generally included more schizophrenic elements than his father's. However, at certain points in Mr. B's history (e.g., the 1966 episode) a major mistake in diagnosis could have occurred by overfocusing on the symptom picture when schizophreniform symptomatology was prominent.

The most gratifying similarity has been their response to lithium. Those who view mania and schizophrenia as fundamentally different disease processes probably would not have used lithium with Jim B (11–15). We believe that use of differential diagnosis scales, particularly reliance on Schneider's criteria, eliminates a number of potential lithium responders, including this patient (11). The reported propensity for acute organic brain syndromes in "schizo-affective" patients receiving lithium was not observed in either man and we believe that this phenomenon has not been widely confirmed (12, 13).

It is our opinion that there are practical advantages to considering schizophrenia and manic-depressive psychosis on a continuum. One can thus approach the decision to use lithium from a quantitative perspective rather than grappling with a diagnostic either-or dilemma. Although we recognize that potential obfuscation of clear diagnostic thinking could result, we find the theoretical and practical cul-de-sacs of the either-or approach more restrictive. We have adhered to the traditional diagnostic term "schizo-affective" deliberately because we feel it is phenomenologically descriptive and represents the highest level of diagnostic certainty presently obtainable in these types of cases.

A weakness in much recent literature on mania is reliance on post hoc propter hoc reasoning. The argument is: a) the patients presented classic symptoms of schizophrenia, but b) they responded clinically to lithium carbonate. Therefore, c) they are actually manic. Such reasoning may be specious, particularly if the so-called schizo-affective and atypically manic syndromes actually represent points along a unified diagnostic continuum rather than admixtures of two unrelated psychotic entities.

We conclude that many psychotic syndromes with both schizophreniform and affective elements may re-

spond dramatically to lithium carbonate. The relationship between mania and schizophrenia, especially at a neurophysiological and biochemical level, has yet to be clarified.

Marital Therapy When One Spouse Has a Primary Affective Disorder

BY BERNARD L. GREENE, M.D., NOEL LUSTIG, M.D., AND RONALD R. LEE, PH.D.

The authors explain why marital disharmony when one spouse has a primary affective disorder is difficult to treat but suggest that such couples can be treated successfully if the therapist is flexible and sets realistic goals. Because of the variability of the disease and the many unsubstantiated etiologies associated with it, the authors recommend a modified general system theory approach to treatment that includes a combination of psychotherapy and somatotherapy.

IN OUR TREATMENT of marital disharmony, a striking group of individuals emerged whose behavior was depressed or hyperactive, sometimes hostile and/or destructive, but whose marriages rarely ended in divorce. It became clear that one of the partners had a manic-depressive illness—now labeled primary affective disorder (PAD). This is the third study of couples with marital disharmony in which one spouse had a PAD (1, 2). (PAD is characterized by alterations of mood, thought, and behavior; this diagnosis has been substantiated by increasing clinical and experimental evidence of a complex psychological and biological etiology [2].) We have found the modified general system theory approach to this problem to be practical because its holistic view enables us to assess and make more effective use of the parts. We also believe our conclusions are important because they are based on years of clinical experience (3, 4).

The sample consisted of 100 upper middle or upper class couples who came for private treatment and/or evaluation from March 1948 to March 1974; 80 couples received therapy. The mean length of observation of the treated couples was 4.92 years (SD = 6.13). There were 100 spouses diagnosed as having a PAD: 40 were classified as unipolar depressive, 18 as unipolar manic,

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Greene is Clinical Professor of Psychiatry, Abraham Lincoln School of Medicine, University of Illinois, Chicago, Ill., and Emeritus Clinical Professor of Pastoral Psychology, Garrett-Evangelical Theological Seminary, Evanston, Ill., where Dr. Lee is Professor of Pastoral Psychology. Dr. Lustig is Associate Clinical Professor of Psychiatry, Center of Life Sciences, University of California, Los Angeles, and Chairman, Department of Psychiatry, Northridge Hospital, Northridge, Calif. Address reprint requests to Dr. Greene, 2375 Toledo, Palm Springs, Calif. 92262.

and 42 as bipolar. Of the 40 unipolar depressives, 7 were men and 33 were women. Of the 18 unipolar manics, 14 were men and 4 were women, and of the 42 bipolar patients, 10 were men and 32 were women. The difference between men and women based on diagnosis is significant ($\chi^2 = 22.83$, $p < .01$).

Despite considerable strides that have been taken in the past decade to understand and manage the primary affective disorder syndrome, large numbers of patients with an undiagnosed PAD present a challenge to psychiatry. All clinicians need to be aware of the ways in which masked depression or hypomanic-manic states manifest themselves. Recently, Feighner and associates (5) published criteria for diagnosing a PAD. We used most of their criteria in the selection of this sample, but in our experience PAD episodes may vary from one to several days to weeks and even months. In the diagnosis of a PAD we have ruled out other psychiatric syndromes secondary to specific crises and depression and/or mania seen in the course of other psychiatric or neurologic illnesses.

GENERAL SYSTEM THEORY

Our current conceptualization has evolved from the medical model, from the insights furnished by the psychodynamic psychologies, and from the general system theory of von Bertalanffy (6). No one model, whether based on a consideration of intrapsychic dynamics, interpersonal relationships, sociocultural factors, or ideological preferences, can describe the transactions within a marriage. All behavior has meaning and all responses are motivated by internal activities. In addition to this intrapersonal system, every individual has meaningful relationships with others (interpersonal system) and lives in a sociocultural matrix (environmental system). All three systems have open boundaries and contain components in constant transactions of varying intensities. Marital disharmony results when the transactions among these three systems create dysfunctional permutations.

One principle of general system theory, "equifinality," is illustrated in the primary affective disorder syndrome by its multiple precipitating factors (7), i.e., the changing manifestations within an individual or the "switch process" (8) of sequential behavior changes.

Intrapersonal System

We have subdivided the intrapersonal system into two subsystems: psychodynamic and biological. Psychoanalytic formulations provide a good source for hypotheses because of the exhaustive scrutiny of the analytic process. The individual with a PAD is characteristically hypersensitive and hyperreactive. The psychological precipitant, whether real or symbolic, may be so slight as to be overlooked or the resulting reaction so strong that the clinician cannot observe the cause.

Until recently, American psychiatry was strongly influenced by the epigenesists—Freud and Adolf Meyer. Freud (9) warned against assuming general validity for his findings: "some of them [these forms] suggest somatic rather than psychogenic affections." He emphasized the similarity of melancholia to mourning, with the addition of a marked tendency to self-reproach and self-revilement and a fall in self-esteem. Subsequent analysts added metapsychological concepts of orality, ambivalent object relationships, narcissistic trauma, etc. Jacobson, who in 1943 stated that patients with depression are "psychologically identical" (10), changed her position 30 years later (11) to state that they are not psychologically or psychogenetically homogeneous.

Because of the importance of the factor of heredity in PAD, the psychiatrist should attempt to trace the generational course of the disease, not only horizontally among the siblings but also vertically, i.e., back to parents and grandparents and forward to children, regardless of age. In a previous study of this subject (1), we found generational support for the diagnosis of a PAD in 70% of our patients.

Most research is now being directed to the neurophysiologic mechanisms—the so-called biogenic amine model of polarity. A critical assessment of catecholamines and PAD has been published recently by Shopsin and associates (12). However, this hypothesis will continue to be useful until replaced by a more adequate one (e.g., one related to the cholinergic-adrenergic balance).

Interpersonal System

We use the term "interpersonal system" to refer to the relationships among spouses, their children, their extended family, and significant others. The mean years of marriage in our sample was 13.93 (SD = 8.00), and for 77% of the couples it was the first marriage for both spouses.

One of the issues raised in this study was the personality structure of the spouses of the marital dyad. We used two dimensions similar to those used by Eysenck (13)—extroversion-introversion and control-noncontrol. When all 200 spouses were placed in one of the four endpoints of the dimensions, 107 were found to be extroverts, 2 were introverts, 70 were controlling, and 21 were noncontrolling. When these personality dimensions are arranged according to their marital dyadic structure, the overwhelming proportion of dyads (61%) shows an extroverted person married to a controlling one. This strongly suggests that the person with a primary affective disorder consciously and/or unconsciously selects an overcontrolling partner to help cope with the severity of his/her mood swings, whereas the overcontrolled, usually obsessive-compulsive, personality seeks the spontaneity of emotional expression of the PAD personality.

The preponderance of the controlling-extrovert dyad supports the notion of a deep symbiotic attachment that takes place when a PAD spouse is involved and suggests a reason for the low incidence of divorce found in this type of marriage. Jacobson (11) suc-

cinctly describes the way people with a PAD and their spouses cling to each other. Another important psychological factor in the tenacity of these marriages is the shame-guilt bind. A frequent observation in the conscious and even unconscious (dream) material is the non-PAD partner's wish for his/her spouse to drop dead. Another psychological variable relates to negative self-concepts. Of the 11 patients in our sample who divorced, 5 had concrete plans to remarry. We feel the present divorce rate would be even lower if the PAD partner had not had anyone waiting. This reinforces the notion that a deep symbiosis is a major characteristic of this type of marriage.

Environmental System

Because of the open nature of the boundaries among the intrapersonal, interpersonal, and sociocultural systems, transactional processes take place in each system that affect human behavior. One of the special features of a person with a PAD is that his/her boundaries are even more open during a hypomanic or manic episode, when he/she is biochemically primed and supersensitive to family transactions and environmental influences. During such periods the slightest external pressure seems to set off intense internal impulse bombardment. Whether or not the environment acts as a triggering device, very destructive behavior can result once a PAD episode begins. This behavior may involve community agencies—trouble with the police, an employer, or employees. The psychiatrist must at times act as an ombudsman.

TREATMENT

Our clinical experience parallels Murphy and associates' (14) i.e., "marked variability of this disease seems to be one of its most striking features." In our study 66% of the marriages were considered to be intermittently incompatible, i.e., they are stable most of the time but are subjected to periods of uproar when the PAD spouse displays gradual to sudden radical changes in mood, thoughts, and/or behavior. Treatment is designed to bring stability back to the marital system as soon as possible and is frequently accomplished by psychotherapy and/or somatotherapy for the PAD spouse and by psychotherapy for the non-PAD spouse.

In the 66% of the couples with intermittently incompatible marriages, 22% were taught to manage a PAD crisis without the therapist. Another 34% were taught to manage most of the PAD mood swings but at times needed the help of the therapist, who was available when needed. The remaining 10% needed regularly scheduled sessions spaced from several weeks to several months apart, a situation that evolves when a couple does not have enough resources to cope with the behavior of the PAD partner. Stabilization for at least 5 years was reached by 10% of the couples. Another 13% of the couples followed the more traditional pattern of durable incompatibility, and 11% of the marriages ended in divorce.

Before any treatment is undertaken the therapist should be prepared for suicidal emergencies. We found that 64% of the patients with a PAD had suicidal thoughts and 43% had seriously attempted suicide before marital treatment was instituted. Inpatient therapy is mandatory if the patient is suicidal, unless there is concerned social support or the condition clears rapidly on medication.

The more experience we had with this type of marriage, the more we came to emphasize preventive work. Our current practice in premarital counseling is usually to advise against marriage when there is a history of a primary affective disorder. It has been our experience that only 60% of the couples follow this suggestion. Marriage to an individual with a PAD involves serious risks: the deep emotional consequences of suicide attempts or suicide, the strong hereditary component, and the intermittent incompatibility of the marriage are emotionally disturbing not only to the spouses but also to the children.

We do not recommend group therapy for a PAD spouse. Members of the group are not aware of the permeability of the ego boundaries of a person with a PAD and can quickly reinforce behavior destructive to this type of marriage. Frequently, the non-PAD partner feels attacked and misunderstood by the group.

Our lack of success in the psychoanalysis of patients with a PAD has led to a combination of psychoanalytic psychotherapy and somatotherapy as indicated. In 1930 Freud (15) predicted that the hope for the future lay in an organic chemistry or endocrinologic approach to psychosis. Even though this future seemed far off, he recommended that every case of psychosis be studied analytically because he believed that the knowledge thus gained would some day direct chemical therapy.

One of the first issues the psychiatrist must decide upon is whether the patient with primary affective disorder needs medication. Many PAD patients with depression and even hypomania tend to have a self-limiting course without medication. Occasionally the patient may need to be hospitalized. Brief ECT may produce significant changes. Our experience as to prevention with lithium is equivocal, but in most cases there is only moderation of mood and behavior. Frequently the non-PAD partner will express a desire that his spouse stop medication and be his "own self."

We have found it valuable to work with the non-PAD spouse in supportive and/or psychoanalytic psychotherapy. Our basic technique is to turn the non-PAD spouse into an assistant therapist and train him for the task of managing the marital system during a PAD crisis. We find that once the non-PAD partner accepts the fact that much of his/her spouse's behavior arises from genetic and biochemical imbalance, there is greater willingness to cooperate. These sessions with the non-PAD spouse are worthwhile because they tend to break the shame-guilt cycle and enable him/her to mo-

bilize more energy in dealing with the realities of the marriage.

We feel that once the diagnosis of PAD is made, the identified patient and the marriage should be viewed as deserving the same long-term commitment as with diabetes mellitus. Both diseases have many unsubstantiated etiologies, show a bell-shaped curve of intensity, and affect all ages.

Psychiatrist-Wife-Mother: Some Aspects of Role Integration

BY MARYONDA SCHER, M.D., ELISSA BENEDEK, M.D., ARDIS CANDY, M.D., KIRA CAREY, M.D., JANET MULES, M.D., AND BERNICE SACHS, M.D.

Throughout her professional life the woman who chooses to combine the roles of psychiatrist, wife, and mother may find them not only compatible but complementary. If she can adopt a philosophy of life that permits her to function in these roles, and if those around her support her activities, she can perform with relative ease and proficiency. Her lifestyle must of necessity differ from that of her male colleagues, but differing lifestyles among members of a profession vitalize the field. A broad perspective is desirable, especially in a profession that deals with the emotional and mental lives of people. Married women and mothers afford such a broadened perspective to the field of psychiatry.

THERE IS AN interplay between the private and public lives of every person. Each sector influences the other. A remarkable document, the March 15, 1973, issue of the *Annals of the New York Academy of Sciences* (1) illustrates this point well. In the first section of this monograph, 12 women from different scientific fields (none of them psychiatrists) described their careers. These women emphasized the impact of mar-

This paper grew out of a panel discussion entitled "Psychiatrist-Wife-Mother: Is Serenity Possible?" presented at the 126th annual meeting of the American Psychiatric Association, Honolulu, Hawaii, May 7–11, 1973.

Dr. Scher is Staff Psychiatrist, Veterans Administration Hospital, 4435 Beacon Ave. South, Seattle, Wash. 98108, and Associate Professor, Department of Psychiatry and Behavioral Sciences, University of Washington School of Medicine, Seattle, Wash. Dr. Benedek is Associate Director, Training and Education, Center for Forensic Psychiatry, Ypsilanti State Hospital, Ypsilanti, Mich. Dr. Candy is in private practice in Bismark, N.D. Dr. Carey is Research Associate, Department of Psychiatry and Behavioral Sciences, University of Washington School of Medicine, Seattle, Wash. Dr. Mules is in private practice, Seattle, Wash. Dr. Sachs is Chief of Mental Health Services, Group Health Cooperative of Puget Sound, Seattle, Wash.

riage and children on their careers and vice versa throughout this work. A similar document about men does not exist. Men do not write about the combination of marriage, fatherhood, and career—at least not in the scientific literature. Perhaps men feel constrained from discussing such subjects in print; perhaps cultural sanctions do not allow them to do so.

Women are not so restricted, especially in recent years. As women have become more involved in the world outside their homes, they seem anxious to share both the public and private aspects of their lives with each other and with men. For example, the panel discussion on which this paper is based was presented at the annual meeting of the American Psychiatric Association in May of 1973 and was scheduled for 7:45 a.m. on Friday, the final day of the meeting. The typical attendance at any panel scheduled for that time is low—often fewer than a dozen people attend. That morning the room was full; every seat was occupied and people were standing around the periphery of the room and in the hall outside. The discussion was lively because so many in the audience were anxious to share their experiences with the panelists and each other.

This article discusses some of the pertinent themes that emerged in that panel and the ensuing dialogues. The themes involve the interplay among womanhood, marriage, motherhood, and the career of psychiatrist. We will offer some guidelines for maximizing effective performance and satisfaction in these multiple roles.

BASIC PHILOSOPHICAL STANCE

The woman who combines marriage, motherhood, and a professional career needs to adopt a philosophy of life that regards these roles as compatible. She must feel that each role is her right as a creative and talented human being. Mental conflict and ambivalence about this issue will deplete the energy she needs to perform her tasks.

The scientific literature offers very few studies to help her establish a positive philosophy toward her lifestyle. Hoffman (2) recently reviewed the literature and found no articles examining the effects of motherhood on professional career. A few authors described the effects of a professional career on motherhood. One showed that middle- and upper-class women who work in careers by choice tend to be overprotective and oversolicitous of their younger children. This behavior drops out as the children reach adolescence. Hoffman points out that such behavior is more likely to be the result of guilt about working rather than the work itself. Other studies show that high-achieving women have high-achieving sons and daughters. Achievement itself does not guarantee equanimity or happiness, but one study she cites indicates that professional women have greater self-esteem and sense of competence than nonworking mothers. Finally, one study examined the effects of marriage on the professional woman and noted that the married women are less lonely and more comfortable in social relationships than their unmarried counterparts. On balance, then, the very sparse existing literature would seem to favor the combination of roles.

Some careers combine with marriage and motherhood more readily than others—the practice of psychiatry is one of them. The philosophical stance of Western psychiatry supports the position of the professional wife and mother. Its basic tenets encourage each individual to attain maximal self-actualization within his or her lifetime by overcoming personal and cultural repressions. It is likely that the female psychiatrist will incorporate this tenet into her personal philosophy of life. In so doing she will be free to pursue her own self-development, and her excellence as a psychiatrist will be measured in her ability to assist others in the same pursuit. Ideally these others include not only her patients but her friends, colleagues, and the members of her family.

The woman psychiatrist seems particularly concerned about the effects of her career on her marriage and children. A pilot study by the American Psychiatric Association's Task Force on Women illustrated these concerns (3). In the study, 35 male psychiatrists were compared with 35 female psychiatrists, and few differences were found between the two groups except in the area of family-career conflicts. Almost 50% of the women reported concern about combining profession and marriage and profession and motherhood. The men did not report such concern. The women handled their family-career conflict by reducing their career demands, working fewer hours, changing to less strenuous and less time-consuming areas of practice, or giving up the care of their children to a housekeeper or parent. Of the women psychiatrists' 44 children, 22 were born after the women had completed their residency training; only 9 of the men psychiatrists' 32 children were born this late. The women in residency tended to be older than the men and had delayed starting their families. Two-thirds of the children were born after the women were 30 years old. Apparently the women attempted to delay motherhood until the strenuous training years were near an end or completed, at which time they were better able to manipulate their professional commitments to mesh with their domestic lives.

This study illustrates the sensitivity and care with which the female psychiatrist approaches her tasks. She is aware of the interplay among various aspects of her life and plans her life accordingly. Her personal life and work become corroborative experiences. She learns in her psychiatric studies the effects of cultural and emotional deprivation, divorce, poverty, intolerance, destructive hostility, illness, and a host of other pathological psychosocial factors. These are not depersonalized phenomena that she reads or hears about in the media but personal and intimate events in the lives of her patients. She can apply what she learns at work at home. Her most important tool in psychiatry is her ability to form mutually enriching and creative relation-

ships. She can use this talent to enhance her relationships with her husband and children.

The roles intertwine—each enhances her proficiency in the other. Her experiences as wife and mother bring personal and intimate knowledge of life's exigencies to her work with patients. They enrich her professional capacities and add depth to her insight and understanding of human nature. It is important that she share her experiences and observations with her colleagues (4). Psychiatry, which needs the knowledge of its female practitioners, has had little input from women. Many of its theoretical distortions could have been prevented or corrected had women been more active in the field.

With the realization that her roles can enhance and complement each other, the psychiatrist-wife-mother is able to adopt a positive attitude toward her lifestyle and organize her life to function maximally in each of her roles.

EXTERNAL SUPPORT SYSTEM

Organization is the key to the performance of the professional who is also a wife and mother, and the most critical aspect of that organization is the external support system with which she surrounds herself. Family, neighbors, community, colleagues, office and domestic helpers, and patients are all part of the system. It is of interest that the husband-father-psychiatrist must also have a strong external support system to function maximally. While models of such systems abound for him, few exist for the woman. A review of the major components of strong support systems follows.

Perhaps the person most critical to the psychiatrist-mother's effective functioning is her spouse. His encouragement, support, and willingness to make compromises are vital. Bailyn (5), in an article about family constraints, pointed out the importance of the lifestyle of the spouse. Professionally qualified women married to men whose work is all-important to them and who consider family matters secondary are not likely to work. It is the wives of men who maintain a balance of commitments to work, family, and society who follow their professional careers. An egalitarian marriage is necessary if dual careers in a family are to coexist successfully.

While the reactions of a woman's spouse are important, those of her children are no less so. Their willingness and ability to adapt to surrogate care, their physical and emotional health, their pride in their mother's accomplishments, their acceptance of her curtailed activities in many areas of their lives, and their independence and sense of responsibility are all reinforcing for her.

Support and help of friends and neighbors are also necessary—someone to take the woman's place in the car pool, someone to check on the new baby-sitter, people who understand why she may not be able to attend the PTA or play bridge or chat leisurely over a cup of coffee, teachers who treat her children like any others, etc. She relies on the good will and understanding of many people around her, but, as in her marriage, reciprocity is important. Friends, neighbors, and acquaintances cannot be expected to respond to her wishes and needs without getting something in return. Often recompense is asked in the form of casual professional services—a curb-side consultation or a query about referrals and resources. If she can provide such an occasional service with grace and sensitivity, she becomes a valued neighborhood resource. It is wisest that she give her services only when asked and only when needed. Many lay people fear psychiatrists, believing them to be omniscient and powerful, and the most casual contact may arouse discomfort and anger. She must be alert to this aspect of her relationships with the people around her and ease their discomfort whenever she can.

The people she hires to provide child and household care are critical in her support system. Her psychiatric experience heightens her awareness of the optimal care needed by her children. The effort and care she takes to select reliable, warm, and honest people will be to her advantage in the end. She is wise to select people whose child-rearing techniques and standards of household cleanliness resemble or exceed her own. In so doing, she will ease her worries about her home and family and be able to function better at work. As is the case in any employee-employer relationship, the people she hires will need some things from her in return—adequate and prompt pay for services rendered, paid vacations and sick leave, personal respect from members of the family, a minimum of criticism, clear guidelines for expected work performance, and thanks for work well done.

A woman's professional contacts, including her employers, coworkers, and patients, are also part of her support system. In a recent survey of the nation's psychiatrists (6), a higher percentage of women than men reported working in salaried positions. While the woman who confines her work to private practice is able to manipulate her own schedule to facilitate her multiple roles, the employed woman must rely on her employer to help her do so. A supportive employer is essential but may be hard to find. Kaley (7), in a study of attitudes toward the dual role of the married professional woman, found significantly more negative attitudes among male professionals than female professionals. Since 89% of psychiatrists are men, most female psychiatrists will be employed by a male psychiatrist and influenced by his attitudes. Schwartz (8) has examined the related needs and attitudes of women and their employers. She documented the greater productivity and creativity of the part-time female employee as well as the lower turnover rate and challenges the existing negative sanctions and attitudes toward wives and mothers who work. Benedek (9), in a paper entitled "The Fourth World of the Pregnant Therapist," illustrated the problems of a psychiatrist-wife-mother working in

a salaried position in which her employers and colleagues held negative attitudes toward her employment. Her experience and the experiences of others (10) stress the importance of a supportive employer and colleagues who understand and appreciate her multiple roles. Often the professional woman needs part-time work, maternity and child care leave, and individualized work schedules. She should make certain that these alternatives are available to her before accepting employment.

When and if she avails herself of such alternatives, coworkers such as other physicians, nurses, and secretaries need to be kept abreast of her schedules, her replacements when she is unavailable, and her future plans. Such communications help to maintain good relationships with colleagues and coworkers, thus enhancing the effectiveness of her work performance. A supportive and coordinated network of coworkers and colleagues is as essential to her as to any physician. It is therefore important that she be sensitive to biases and prejudices among the people who form that network. Those who resent or disapprove of her multiple roles may easily undermine her effectiveness, and it is to her advantage to establish positive rapport and effective working relationships with such people.

Finally, although it is seldom stated in this way, patients form the mainstay in the support system surrounding any psychiatrist. One simply cannot practice psychiatry without the presence and cooperation of his or her patients. Most patients adapt easily and quickly to a female psychiatrist. Some prefer a woman, just as others prefer a man. One recent study (11) showed that people in general, and men in particular, were more open to women in general than they were to men. If this holds true in psychiatry, the female psychiatrist would appear to have at least an initial advantage over her male colleague in working with patients. Whether she does or not, she must consider the needs and sensibilities of her patients, just as she does those of the other people surrounding her. Her patients also need to know her work schedules, her plans for vacations and leaves, and her replacements when she is unavailable. She is wise to share with them the fact that she chooses to function in multiple roles. Patients often appreciate having a psychiatrist who is also a wife and mother. They may see this as evidence that she is a relatively normal and human person capable of greater understanding and empathy. Patients are usually considerate if they know their psychiatrist functions as a wife and mother as well as caring for them. They are less likely to make unreasonable demands on her time and energies and are more likely to work in a collaborative, responsible fashion within the psychotherapeutic relationship.

In summary, then, the psychiatrist-wife-mother has a potentially supportive network of people including her husband, children, employees, friends, neighbors, colleagues, coworkers, and patients. She must foster and maintain good relationships with these people if their support is to be forthcoming. When it is, and when other life stresses are minimal, she can function with relative ease in her multiple roles.

CHANGING RESPONSIBILITIES

The demands and responsibilities of the psychiatrist's roles shift over her lifetime, and she must plan her schedules and activities accordingly. Psychiatric training and the birth of children often overlap. Many women, knowing the genetic and environmental disadvantages that children of older mothers may suffer, feel that they have prolonged motherhood as long as is wise by the time they reach residency. In Roeske's sample (3) only half of the women waited until the completion of their training to begin their families. The problems encountered during this period of life include finding a residency program flexible enough to meet the need for maternity leave and part-time schedules (12), hiring adequate child care for completely dependent children and paying for this care, and stretching limited time and energy to meet the heavy demands from both the home and the residency training program.

As their children reach school age, most women have completed their training. The type of child care that is needed changes. The children are at school for several hours a day, during which time neither the mother's care nor surrogate care is needed, although school vacations, holidays, and periods of illness still require the presence of someone. The psychiatrist-mother may choose to schedule these times to be with them herself. If so, she will need a flexible work situation. She cannot expect to work, spend time with her husband and children, and do all the housekeeping chores. Housework and gardening may be shared by all members of the family but almost always need to be supplemented by outside help. Dividing and assigning these tasks will require organizational skills.

As the children reach adolescence, and their need for supervision lessens, she may be well into her career. Most women find that this is not a good time to reduce their investment in their children significantly. Rather, their style of interaction shifts. Adolescence, with its burgeoning independence, identity crises, peer group pressures, and hormonal upheaval may be a trying time for young people, and the availability of a trusted adult is important. It is wise for parents to maintain a sensitive, vigilant interest in their children during this period; the psychiatrist-mother is likely to be aware of this need and responsive to it.

Once the children leave home, her responsibilities for their needs diminish significantly and she is freer to pursue her other interests. Her career may now gain new emphasis and she may increase her workload. If she does so, the increase in her earnings will ease the financial burdens characteristic of this period of life, e.g., college costs, marriage expenses, and the care of aging parents. She and her husband may now pursue mutual interests that have long been thwarted through

the child-rearing years. She has time for reflection, reassessment, and leisure. While menopause, with its hormonal and potential emotional imbalances, is near, involvement in her career, increased interaction with her spouse, and the lessened demands of motherhood may ease her through this transitional period of her life. She can still allow time to share the post-separation joys and crises of her children—to be mother of the bride or groom, to be grandmother-helper with the new baby.

As she and her husband age and approach death, her career may once again sustain both of them. Barring ill health she may practice as long as she lives and maintain her independence if she is widowed. Hoffman (2) suggested that "a woman with combined roles may retain an enthusiasm and creativity in her work even in her very mature years when many men who have constantly pursued their careers become bored, stagnant and bureaucratized." Because the practice of psychiatry is not strenuous, she may be able to maintain an active professional life long after people in other fields are forced to retire, while continuing to have a rich interchange with her husband, children, grandchildren, other family members, and friends. Of course, she may choose to retire from active professional life and live her last years involved in other activities. If she does so, it is likely that she will look back on the completion of her multiple tasks with the sense of accomplishment and pride that a varied and productive life brings.

Some Problems in Learning To Do "Good Psychotherapy"

BY MAGNUS LAKOVICS, M.D.

In a discussion of some problems that psychiatric residents encounter in learning to do good psychotherapy, the author compares learning techniques of medicine and those of psychiatry. He concludes that one of the most difficult experiences for the psychiatric resident is learning tolerance for ambiguity and uncertainty.

DURING RESIDENCY training, I became very concerned with the problem of learning to do psychotherapy well. I wrote the body of this paper at that time; however, I could not finish the paper since my residency training had not yet ended and my thinking in this area was not fully developed. Consequently, I put the paper aside. John P. Spiegel's Presidential Address in the July 1975 issue of the *American Journal of Psychiatry* (1) stimulated my thoughts again and enabled me to conclude my paper.

Learning to do what I will call "good psychotherapy" is by no means a minor task. Considering the numerous types of psychotherapy advocated by the various schools of psychiatry and psychology for every kind of disturbance from schizophrenia to the prob-

When this paper was written, Dr. Lakovics was Clinical Instructor of Psychiatry, State University of New York, Upstate Medical Center, Syracuse, N.Y., and Staff Psychiatrist, Veterans Administration Hospital, Syracuse, N.Y. He is currently Instructor of Psychiatry, Department of Psychiatry and Behavioral Sciences, Eastern Virginia Medical School, Norfolk, Va. Address reprint requests to him at 4149 Thistle Circle, Virginia Beach, Va. 23462.

The author wishes to thank Dr. Donald Oken for his assistance.

lems of the dying, one wonders how the novice ever figures out which type of therapy is best for a particular patient, let alone how to practice this therapy well. In this paper, I will delineate some of the difficulties encountered by a novice physician in learning to do good psychotherapy. Certainly, we all share in the curiosity of how to do our job well; if not, perhaps Samuel Goldwyn was right when he said that anyone who spends money on a psychiatrist should have his head examined.

DISCUSSION

Before I entered psychiatric residency training, I was taught in medical school that people "had diseases." I learned that some diseases had known causes, while others were idiopathic. I also learned that once we could establish that Mr. X had appendicitis we could then proceed to treat him. I also learned that there are various indications for one type of treatment versus another. My experiences with medicine were that the problem of what to do fell in one of three categories: 1) there is a generally agreed upon definitive treatment for Mr. X's disease; 2) there is no known treatment for Mr. X's disease; and 3) there are treatments for Mr. X's disease but it is questionable whether they will improve his condition. The goal, of course, is to restore Mr. X's health or, if this cannot be done, to make him as comfortable as possible. With this kind of background and consciousness I began my first extended psychotherapeutic encounter with a patient during my first year of residency training.

Mr. A, one of my first patients, came to the Adult Psychiatry Clinic[1] with an initial complaint of continual feelings of worthlessness and inability to tolerate well any compliments or positive feelings extended toward him. He wished to talk with me to better understand this peculiar state of affairs, hoping to rid himself of these problems. In this case my goals for Mr. A were similar to the goals for Mr. X, i.e., to restore or increase the patient's well-being. However, it quickly became apparent to me that the means, as well as my conceptual understanding of the nature of the distress, had to be quite different. One of the problems of recent medical school graduates is that we still prefer to speak in the language of diagnosis, indications, and treatment, even in relation to problems of the sort presented by Mr. A, since we are most familiar with this language. At times this can be more confounding than helpful in dealing with problems such as Mr. A presented to me in the clinic. The tendency to use medical terminology is one of the first problems I struggled with as a beginning psychotherapist.

Learning how and when to treat in medicine is by no means simple, but at least it is conceptually within reach. One of the most frequently used ways to teach is bedside teaching by experienced instructors. Sometimes how a patient should be treated is debatable. However, there are certain generally known things one should almost never do—e.g., give insulin to a hypoglycemic patient. Procedures that, almost without exception, are wrong are usually pointed out to the student very quickly by his instructors. If nothing else, this teaches the student what he should not do, the benefit being an absence of doing what is wrong. In psychotherapy supervision (supervision by faculty members of patients I saw in the clinic) I do not think I was ever told that what I was doing was wrong. This could be because I had been doing everything right, but a more likely possibility is that the problem of knowing what is wrong in psychotherapy is much more complex than it is in medicine.

It also occurred to me that I could think of almost nothing, with the exception of violations of the law and professional ethics, that could be wholly agreed upon by my faculty as being the wrong thing to do in psychotherapy. (I suspect this is true of most psychiatric department faculties across the country.) Perhaps I was not aware of all of the faculty's consensually validated opinions about psychotherapy. This may be one of the problems of learning good psychotherapy, i.e., the faculty only talks about what they do not agree on. I do not mean that I would prefer more dogmatism; I do mean to convey the difficulty in situating himself that a novice in this field has.

I also feel there are few things that would generally be considered as always correct in psychotherapy. One psychoanalytically oriented supervisor might say, after my sessions with Mr. A, that if we did not get to his castration fears then we would only have scratched the surface. Another supervisor, oriented more toward autonomous psychotherapy (a type of psychotherapy which has as its main goal the preservation and expansion of the patient's autonomy [2]), might say, "Why do you want to talk about castration if the patient doesn't?" One could say that the analytic approach is clearcut—learn by observing the expert. Then one gets the idea that the resolution of the sorts of problems patients present to psychotherapists is completely independent of the therapist's approach to them. This may be true, but it is certainly different from the situation with Mr. X's appendicitis. Both surgeons and internists would generally agree that therapy for appendicitis is usually surgery. The novice in psychotherapy faces a much more difficult task in learning; he cannot completely rely on the experience of his colleagues to help him treat either the usual or unusual problems that his patients bring to psychotherapy.

Another source of learning in psychotherapy is the nonresearch literature. An interesting quote from a book on psychoanalytic technique edited by Menninger and Holtzman (3) very poetically gives us a sense of how a patient may view the analytic posture in inducing regression.

[1]The Adult Psychiatry Clinic, Upstate Medical Center, Syracuse, N.Y., is primarily a self-referral clinic staffed by trainees (psychiatry residents, interns, psychology interns, and medical students) and supervised by the faculty of the Department of Psychiatry.

With half a laugh of hearty zest
I strip me off my coat and vest.

Then heeding not the frigid air
I fling away my underwear.

So having nothing else to doff,
I rip my epidermis off.

More secrets to acquaint you with
I pare my bones to strips of pith.

And when the exposé is done
I hang, a cobweb skeleton.

While you sit there aloof, remote,
And will not shed your overcoat. (pp. 60–61)

Allen Wheelis, an existentially oriented psychotherapist, views psychoanalytic therapy very critically and sees its outcome as anything but illuminating (4). He says,

> When, however, in therapy a life story is reworked to expose the forces which "drove" one to do as he did, emphasizing traumas which twisted him and shaped defenses, hidden constraints, situational and libidinal, which required that he react in the way he did and in no other—in all this, too, one is rewriting the past, is taking a story which must have contained some elements of freedom and responsibility and retelling it in terms of causes lying outside one's control, so teaching the patient to see himself as the product of inner and outer forces. Where he feels himself to be the author of action, his analysis will reveal him as an object being acted upon. He then comes to regard himself as being lived by unknown and largely unknowable forces. As consolation prize he may acquire the capacity to guess at the nature of those obscure forces that move him. But only guess. He must not attempt seriously to bear witness to that which, by definition, he cannot know. He must remain forever the dilettante, making modest conjecture at the gusts which blow him this way and that. He becomes not only an object but opaque, most necessarily to himself. (pp. 65–66)[2]

The literature is filled with such variations of approaches to psychotherapy and with endless criticisms of the various approaches. In addition one may find in the literature profoundly different approaches to very similar clinical problems. Certainly one would not expect a psychoanalyst like Karl Menninger and an existential psychotherapist like Allen Wheelis to agree; however, a novice learning psychotherapy deals with a particular patient's problems, not the conflict between analytic and existential approaches. Thus, even though I may be familiar with both approaches, the confusing question of how I should assist my patient in resolving his problems is still unanswered.

Certainly, if the novice has difficulty in finding what he ought to do from his supervisors and the nonresearch literature, he can always turn to the research literature to find the answers. Let us consider the problem of Mr. A and see if we can find research data that could help me plan a course of action in assisting him. His two primary problems—habitual feelings of worthlessness and intolerance of positive regard—must first be classified in order to find research data to compare how his class of problems was dealt with across a wide sample of different solutions. Into which class does my patient fit? Of course, I first have to familiarize myself with all the ways to classify patients. However, when one undertakes this task one encounters a whole new set of problems. One has to ask whether classificatory schemes are useful besides being valid and reliable. Even if they are valid and reliable (since similarities and differences can be found in any two or more persons in the world), the question of whether classifying my patient is useful will depend on my results.

Let us say this patient's class of problems falls best into the category of depressive neurosis. Freedman and Redlich (5) sum up the literature on depression by saying,

> There is no general agreement as to preference of organic or psychosocial methods of therapy; even in the individual patient, it is often difficult to come to a decision. Our overall recommendations are to treat mild depression by psychotherapy and severe cases by a combination of psychosocial and biological treatment. (p. 556)

From this we can at least say that psychotherapy is possibly the best method of approach to my patient's problems.

The job of finding out what to do in psychotherapy with this patient still remains. What kind of psychotherapy should be used—psychoanalytic, existential, Gestalt, client centered, rational-emotive, or autonomous psychotherapy? This is by no means a complete list of all available psychotherapies. Again Freedman and Redlich (5) sum up our dilemma in regard to the research literature:

> The psychosocial therapies in particular have not been thoroughly evaluated. In any case, there is no "hard-nosed" documentation of their effectiveness. There are very few comparisons of treated and untreated cases. . . . In most cases, evaluations are made by the therapist himself, who is bound to be a subjective optimist and inclined to overestimate his successes and deny his failures. In the literature, there are surprisingly few reports of failures. (p. 300)

As you can see, the novice is not shown the road to nirvana through the research literature either.

Finally, we can say that there are many many different ways to bake a cake and final judgment of its quality should perhaps be left to the consumer. The patient may be our only qualified guide to the problem of knowing whether what we did in therapy was good or bad, i.e., whether we helped him, did nothing, or made things worse. However, one of the first things we are told when we enter the field of psychotherapy is that

[2]Reprinted from *Commentary*, by permission; Copyright © 1969 by The American Jewish Committee.

the patient's satisfaction with your work is a poor guide to its quality. This is attributed to the problem of transference, since the patient may unconsciously and symbolically identify the therapist with some previously significant person in his life with whom he has either had or fantasized a very positive relationship. You may also be seen by him as an all-knowing and infallible savior. Implicit in this rationale is the idea that patients do not know what is good for them—that you are the doctor and are therefore supposed to know what is good for the patient. However, I do not necessarily believe that the doctor always knows best.

CONCLUSIONS

I have tried to illustrate some of the problems that face a novice physician in attempting to learn to do good psychotherapy. Having finished my residency and started a private practice, in addition to working in a teaching hospital and being on the faculty of a medical school, I feel that I know when I do good psychotherapy.

Perhaps Alexander Pope, in *An Essay on Criticism*, best recognized the general dilemma of human existence with respect to knowledge when he wrote:

> A little learning is a dangerous thing;
> Drink deep, or taste not the Pierian spring:
> There shallow draughts intoxicate the brain,
> And drinking largely sobers us again.

With experience and "drinking deep" one gains perspectives that never completely elucidate the morass of confusion and ambiguity. The recognition that psychotherapy and being a psychotherapist must entail ambiguity is perhaps the hardest of all lessons to learn for a novice physician engaged in the enormous task of learning to do good psychotherapy. Spiegel, in discussing the problem of psychiatry as a high-risk profession (1), best sums up this general dilemma for the psychiatrist and the psychotherapist,

> Because of the large number of variables underlying any type of human behavior, our therapeutic decisions are always taken in the context of a certain amount of ambiguity. Since the data available are never sufficient, we have to learn to live with uncertainty. Clinical judgment, based on training and experience, makes the uncertainty manageable, but *every decision we make is a risky decision*. (p. 697)

It is precisely this uncertainty which makes the task of learning to do psychotherapy well such an unsettling experience for the inexperienced. However, it is also this uncertainty and ambiguity that characterizes the everyday life of the experienced, well-trained, and effective psychotherapist.

Physicians' Erotic and Nonerotic Physical Involvement with Patients

BY JUDITH ADAMS PERRY, M.D.

The author surveyed 164 female physicians to determine their attitudes and practices regarding erotic and nonerotic physical contact with patients. Compared with a previous study of male physicians (1), more female physicians believe in and engage in nonerotic touching, but fewer believe in and engage in erotic touching. None of the female physicians reported sexual intercourse with patients as compared with 11% of the male physicians in the previous study.

FOR 24 CENTURIES, ethical standards have prohibited doctors from engaging in sexual intercourse with patients (2–4). Only a few authors have openly refuted this guideline (5, 6).

Kardener and associates (1) studied 460 male physicians and found that most of them did not believe or engage in nonerotic touching, but 5%–13% engaged in some kind of erotic behavior with their patients. Kardener and associates' study stimulated thought about the female physician, whose role appears to have unique qualities that distinguish her from her male colleagues (7, 8).

Are there significant differences between the sexes in beliefs and practices regarding physical contact with patients? What are women's attitudes toward this delicate area of the doctor-patient relationship? The present study was designed to parallel and expand Kardener and associates' research by examining these questions.

METHOD

The 24-item questionnaire used included 9 items about beliefs and practices regarding nonerotic contact with patients (defined as hugging, kissing, and affectionate touching) and 9 items about erotic contact (defined as behavior primarily intended to arouse or satisfy sexual desire). Six items focused on treatment of sexual problems. I also requested demographic data. Most responses used the following scale: never, rarely (less than 5% of professional experience or opinion), occasionally (less than 25%), frequently (more than 50%), and always.

The questionnaire was mailed to a systematic random sample of 500 female physicians, half in New York and half in California (9). Responses were anonymous. Statistical analysis was done by chi-square tests.

RESULTS

General Data

Thirty-three percent (N=164) of the 500 physicians responded, and there were 156 usable questionnaires (2 respondents gave wildly exaggerated responses and 6 responses were incomplete). One letter of protest against this type of research was addressed to Loma Linda University.

The age distribution of the respondents was as follows: under 30, 18%; 30–39, 30%; 40–59, 38%; and over 60, 14%. In contrast, 75% of the male physicians in Kardener and associates' study were in the 40–59 age group. The women respondents were significantly younger ($p<.01$).

Fifty-six percent (N=84) of the female physicians were married, compared with 86% of the male physicians ($p<.01$). More women than men were single (27% versus 3%, $p<.01$). Eleven percent of the female respondents were divorced or separated and 5% were widowed.

Seventeen specialty groups were represented among the female physicians. Results for each item were tabulated for the group as a whole as well as the four specialties with the greatest representation: pediatrics, psychiatry, general practice, and internal medicine.

Years in practice indicated by the 150 physicians responding to this question were as follows: 1–10 years, 53%; 11–15 years, 9%; 16–24 years, 21%; and over 25 years, 17%. Compared with Kardener and associates' study of male physicians, more women had been in practice 1–10 years ($p<.01$), fewer for 11–15 years ($p<.01$), and essentially the same number for more than 15 years.

Treatment of Sexual Problems

Table 1 summarizes the involvement of the female physicians in my sample and the men in Kardener and

associates' study in treatment of sexual problems. Frequency of attempted treatment of sexual problems was not related to state of residence, marital status, or age. Of additional interest, female internists attempted to treat such problems less often than the male internists in Kardener and associates' study ($p<.01$).

Nonerotic Behavior

Responses to 2 questions regarding nonerotic behavior are presented in tables 2 and 3. I also asked 2 questions regarding nonerotic contact to determine physicians' comfort in touching someone of the same

sex versus the opposite sex; no difference was found. The women physicians under 30 years of age believed and engaged in nonerotic touching more often than women physicians above 50 ($p<.01$ and $p<.05$, respectively).

Among the female physicians, no relationship was found between belief in or practice of nonerotic touching and specialty, state of residence, or marital status.

Sixty percent (N=90) of the sample replied to an open-ended question asking under what circumstances nonerotic physical contact (holding, hugging, or kissing) might be beneficial. The circumstance described most often (39%) was to "reassure, empathize." Twenty percent reported "crises" (such as bereavement or congratulations) and 20% reported young or elderly patients. Six percent of the respondents (all psychiatrists) indicated that nonerotic physical contact might be appropriate with schizophrenic, agitated, depressed, or passive-dependent patients. One psychiatrist commented, "When patient initiates physical contact, nonresponsiveness would be read as rejection." Eight percent felt that nonerotic physical contact would not be beneficial under any circumstances. For example, an ophthalmologist replied, "I'm too busy to even think about such things. My practice is confined between the upper and lower lids."

Erotic Behavior

Two percent of the physicians believed erotic contact with patients was beneficial. Female physicians believed and engaged in erotic behavior significantly less often than the male physicians previously studied ($p<.01$ and $p<.05$, respectively). Most female and male physicians indicated that erotic behavior should never include intercourse with a patient (98% and 95%, respectively).

Physicians were asked to indicate the actual number of their involvements in erotic behavior with patients, excluding intercourse. One female physician (a pediatrician) responded affirmatively, indicating 1 patient. Eleven percent (N=33) of the male physicians responded affirmatively, with 70% of this group indicating fewer than 5 patients. None of the female physicians reported coital involvement, whereas 11% (N=33) of the male physicians acknowledged coital involvement.

Sixty percent (N=94) of the respondents replied to the open-ended question, "Under what circumstances might erotic behavior be utilized in treatment?"; 77% of these respondents indicated that erotic behavior is never beneficial. The other 23% cited such circumstances as "wise teaching, never by indulgence," "specific sexual problems," "treatment of sick M.D.s," "extreme feelings of inadequacy," "sex education involving two partners, such as Masters and Johnson," "not unless willing to continue rest of life," and "undecided."

DISCUSSION

Half of the female physicians believed in nonerotic touching; 2% believed in erotic touching. By comparison, the previous study (1) revealed that fewer male physicians believed in nonerotic touching. However, more male then female physicians believed and engaged in erotic touching. Fewer women than men attempted to treat sexual problems in their practice. More younger women than older women touched patients. Female physicians' attitudes toward touching were not related to the sex of the patient, area of specialty, marital status, or geographical location.

Two variables should be discussed when one compares this study with that of Kardener and associates. The female respondents in this study were younger than their male respondents. Also, the women represented 17 specialties (including pediatrics), while there were only 5 specialties (excluding pediatrics) represented in the male sample. The one woman who indicated erotic contact with a patient was a pediatrician.

Physicians have definite and sometimes opposing viewpoints regarding nonerotic and erotic involvement with their patients. Male physicians do not believe in erotic involvement but in practice do become involved, while female physicians consistently oppose erotic involvement.

* Multiple attempters.

unusual attempt methods, which might suggest falsification, supports the validity of these rates.

In addition to reporting actual attempts, 64.8% of the sample reported that on at least one occasion they had thought about attempting suicide. The methods considered encompassed a wide range, some spectacular (e.g., crashing into the White House in an airplane) and some mundane (e.g., "I thought of taking some pills"). Of particular interest was the high frequency among those reporting suicidal thoughts of contemplated suicides involving automobile accidents (25.1%). Also common were lengthy descriptions of precise, meticulously planned, step-by-step procedures leading to "certain death"—often with an explanatory remark at the end stating, "but I never would do it."

DISCUSSION

The high number of suicide attempters in this study suggests that, at least among college students, suicidal behavior may be more prevalent than previously hypothesized. It is thought that college students have higher suicide attempt rates than same-age cohorts without college experience (1–5), and such a comparison needs further exploration. Since these data are for young men and women with a fairly long average life expectancy, one would strongly expect that the prevalence of suicide attempters would increase for these college educated cohorts as they grow older and have more time to join the group of attempters. This increase would be attenuated only by the death rate, including deaths from successful future attempts.

Data about suicidal thoughts confirm the common suspicion that many people think about suicide at some time or other. The high incidence of self-destructive thoughts involving automobiles supports investigations suggesting that many automobile accidents are intentional or subintentional suicides (25).

These prevalence data lend themselves to different interpretations. One interpretation is that the rate reported is also indicative of the rate for college students of the same age of other generations. Since comparative data are not available for past years, the validity of applying these findings to other cohorts cannot be determined. An alternative interpretation is that the rate reported reflects uniquely the behavior of these particular cohorts of 1972–1973 college students. This latter interpretation is consistent with the reported increase in attempts at particular colleges and universities (5). A complete study of various cohort differences might use more sophisticated methods than this investigation, such as the cross-sequential design developed by Schaie (26). This method calls for repeated data collection from different-aged cohorts to compare age-related and cohort-related changes.

Overall, this study indicates that it would be fruitful to supplement current annual incidence statistics with prevalence data from retrospective studies to gain a more comprehensive picture of the extent of suicidal behavior. The rate observed here for college students is so high in absolute terms that the problem of suicidal behavior among college students may warrant serious attention. The high rate also underlines the need for further investigation to determine the extent to which the data reported here are indicative of the lifetime prevalence of suicidal behavior in the population at large.

Psychiatric Test Assessment of Patients with Psychomotor Epilepsy

BY E.A. SERAFETINIDES, M.D., PH.D., AND DIANA G. CHERLOW, M.A.

The authors evaluated the psychiatric status of 31 patients who had temporal lobectomies and 6 patients who received implantation of depth electrodes for relief of epileptic seizures. Results showed a general postoperative improvement in overall psychopathology (measured by the Brief Psychiatric Rating Scale) and in depression in particular; however, depression tended to recur with the passage of time after lobectomy.

THE METHODOLOGICAL and conceptual difficulties encountered in studying psychiatric aspects of psychomotor epilepsy are well known (1–4). In this paper we report the results of a psychiatric study of a sample of epileptic patients selected on the basis of the following strict criteria: presence of psychomotor types of seizures in which automatisms are at least part of the seizure pattern; EEG evidence of temporal lobe focus of seizure activity; lack of therapeutic response to long-term anticonvulsant medication; IQ above 70; and absence of radiological evidence of a space-occupying lesion or arteriovenous malformation (5).

Dr. Serafetinides is Professor, Department of Psychiatry and Brain Research Institute, Center for the Health Sciences, University of California, Los Angeles, Calif., and Associate Chief of Staff, Research, Brentwood Veterans Administration Hospital, Wilshire and Sawtelle Blvds., Los Angeles, Calif. 90073. When this work was done Ms. Cherlow was Assistant Research Associate, Brain Research Institute, University of California, Los Angeles, Center for the Health Sciences; she is now a graduate student in the Department of Psychiatry, Rutgers Medical School, Piscataway, N.J.

The patients selected for study were evaluated through implanted electrode techniques for possible neurosurgical treatment. They were also given the following tests: the Brief Psychiatric Rating Scale (BPRS) (6), as an index of overall psychopathology; the Iowa Hostility Inventory (IHI) (7), as an index of hostility (since aggression is frequently seen in patients with such seizures); and the Zung Self-Rating Depression Scale (SDS) (8, 9), as an index of depression to validate postoperative clinical impressions. Results of speech and memory assessment of these patients are reported in another paper (10). Informed consent was obtained from the patients for all procedures employed in this study.

METHOD

Thirty-one epileptic patients who had had an anterior temporal lobectomy and 6 patients who had received temporal lobe depth electrode implantations took the BPRS, IHI, and SDS. Data on sex, handedness, and treatment received are given in table 1. In addition to these tests, data were collected on the patients' education, marital status, employment, ability to drive (used as an index of rehabilitation) and other characteristics. Each patient was also evaluated clinically for seizure relief, mental status, and neurological abnormalities. These clinical findings were reduced to two scales. One measured seizure relief: each patient was given a rating of 0 if he no longer had seizures, 1 if he had no more than 5 seizures per month, 2 if no more than 15 per month, and 3 if he had seizures more frequently than 15 times per month. The other scale classified patients on the basis of neurological problems and/or memory deficits noted in the neurologist's follow-up examination. A score of 0 represented no deficits or a very minor one; 1 represented two mild deficits or one severe one; and 2 represented more than two mild or one severe problem (e.g., aphasia or hemiplegia).

Seven comparisons were made between subgroups of the patient sample.

1. Right- versus left-lobectomy groups (only right-handed patients included).
2. Left- versus right-handed patients.
3. Preoperative versus postoperative results.
4. Postlobectomy patients versus implantation patients.
5. Recent versus nonrecent lobectomy patients ("recent" defined as two years or less since operation).
6. Male versus female lobectomy patients.
7. Lobectomy and implantation patients versus normal and psychiatric patient population results.

Factors such as marital status, employment, and ability to drive were also examined in relation to patient sex.

TABLE 1
Sex and Handedness of Patients Who Received Lobectomy or Electrode Implantation for Seizure Relief

Patient Group	Number	Sex		Handedness	
		Male	Female	Right	Left
Right lobectomy	22	12	10	16	6
Left lobectomy	9	6	3	7	2
Electrode implantation	6	4	2	3	3

RESULTS

The Brief Psychiatric Rating Scale

Table 2 shows significant results from the BPRS. The preoperative lobectomy patients tended to show more psychopathology than the postoperative group. Although there were no overall male-female differences on the BPRS, females who were not employed showed a greater incidence of psychopathology than those who were. The BPRS also showed significant differences between groups of males in that males who could drive showed less psychopathology than those who could not.

The Iowa Hostility Inventory

There was only one significant result from the IHI. Employed females were less hostile than unemployed females (mean scores 1.0 and 5.0, respectively; $p<.05$). It is interesting that, as was also shown by the BPRS and SDS ratings, employment played a significant role in the psychiatric health of the women in this study.

The lack of preoperative and normative data for this test made impossible a number of comparisons, which may be considered in future studies.

The Self-Rating Depression Scale

Table 3 shows significant results from all comparisons made between scores of subgroups on the SDS. There was significantly more improvement in postlobectomy patients than in both preoperative lobectomy patients and patients who had had only an implantation. There was no difference in the amount of depression exhibited by both of these latter groups. One can conclude that the lobectomy relieved some of the depression that these patients experienced prior to the operation.

Patients who had had a lobectomy within the two years prior to the study tended to be less depressed than those operated on longer ago. Whereas recent lobectomy patients showed less depression than preoperative patients, there was no difference between preoperative patients and postlobectomy patients who completed the SDS more than two years after surgery.

These findings indicate the need for regular rehabilitative and psychotherapeutic follow-up to prolong the beneficial effects of lobectomy on depression. Such a

systematic follow-up would also provide a much-needed test of the effects of this operation on depression in epileptic patients.

Male postlobectomy patients were less depressed than female ones. Since Zung (9) found no sex-related differences in the normal and patient populations he studied, we further analyzed these findings in terms of marital status, employment, and the ability to drive. Single women were not found to be any more depressed than married women or than single men. Unemployed females were not more depressed than employed ones, but they were more depressed than unemployed males. Finally, females who could not drive were more depressed than both females who had licenses and males who did not. These are interesting results, since they show that epileptic men do not suffer a greater loss of self-esteem than epileptic women from confinement and dependence due to inability to work or drive; indeed, if anything, men lose less self-esteem. These observations as well as those on the influence of employment on women patients are intriguing, but additional research is needed before they can be fully interpreted.

Neurological Findings

The difference in frequency of seizures between the postlobectomy patients, who had fewer seizures, and those patients who received implantations ($p<.002$) is further testimony to the importance of the operation in such patients. There were no other group differences related to seizure frequency.

There was a laterality effect—patients who had right lobectomies showed fewer neurological abnormalities and memory deficits than those who received left lo-

bectomies ($p<.002$). This difference held for all postlobectomy patients ($p<.002$) and for right-handed postlobectomy patients only ($p<.01$). Thus patients receiving a lobectomy of the dominant hemisphere are more neurologically impaired than those receiving a nondominant lobectomy. These clinical findings were supported by the results of more formal memory tests administered to these patients (10).

Training Community-Based Paraprofessionals as Behavior Therapists with Families of Alcohol-Abusing Adolescents

BY JOSEPH D. TEICHER, M.D., RUTH D. SINAY, PH.D., AND JEROME S. STUMPHAUZER, PH.D.

To combat the increase in chronic alcohol use among adolescents in a large metropolitan area, community-based paraprofessionals were trained in behavior therapy and treated these adolescents and their families in the home. Preliminary evaluation of the program revealed encouraging results. This training supplied structure for the paraprofessionals' interventions with families and provided them with skills they are continuing to use in their community work.

ALCOHOL ABUSE and dependence among adolescents is fast becoming an alarming national concern; alcohol abuse is felt to be the nation's number one drug problem (1). Recently, the subject of teenage alcoholism has been featured in newspapers, magazines, films, and on television (2–6). Within the past 3 years many adolescents who came to the Los Angeles County—University of Southern California Medical Center with various psychological problems admitted to more than casual use and abuse of alcohol. To assess the trends and extent of drug abuse, we conducted a survey of 200 drug abuse agencies in Los Angeles. The agencies' responses suggested a continuing or increased amount of drug abuse among teenagers, a dramatic increase in alcohol abuse, and increased use of indigenous paraprofessionals, with a need for more (7).

There is considerable suggestion in the literature that drug abuse is learned behavior. Cahoon and Crosby (8) and Crowley (9) have presented interesting theoretical views of the particular psychological learning variables at work in various kinds of drug abuse. More direct evidence of the learning of alcohol abuse has been found by Stumphauzer (10), who has conducted structured behavior analysis interviews with teenage drinkers. He noted the presence of strong modeling and reinforcement, with little self-control

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are with Los Angeles County—University of Southern California Medical Center, 1934 Hospital Place, Los Angeles, Calif. 90033, where Dr. Teicher is Director, Child/Adolescent Psychiatric Services, Dr. Sinay is Director, Child/Adolescent Psychological Services and Training Programs, and Dr. Stumphauzer is Staff Psychologist. The authors are also with the Department of Psychiatry, University of Southern California School of Medicine, where Dr. Teicher is Professor, Dr. Sinay is Assistant Clinical Professor, and Dr. Stumphauzer is Associate Clinical Professor.

The authors wish to thank Lupe Hernandez, Janice Lang, Rubin Rogers, and Esteban Veloz for their participation in the paraprofessional program.

and sometimes delayed punishment. Unlike other types of teenage drug abuse, the family often models, supplies, and reinforces alcohol use. Since alcohol abuse among adolescents is seen as a family-related problem, treating the adolescent with his family, and particularly at home, seemed a natural therapeutic strategy.

Family therapy in general continues to be a growing method of treatment (11–14). In particular, behavioral family therapy or family contracting is now finding wide acceptance (15–18). The assumption is that family members control, maintain, and "teach" each other a wide variety of complex behaviors, and further, that in order to change a child's or adolescent's behavior, the entire family and their exchange of controls should be the focus of intervention. Behavior therapy approaches to the treatment of alcoholism have been recently reviewed (19); it is noteworthy that, to our knowledge, no one has yet reported the use of behavior therapy with adolescent drinkers.

Considering the extent of alcohol abuse, it is apparent that not enough professionals are available to provide treatment to those in need. Trained paraprofessionals have provided direct, adequate, and inexpensive services to the community. Paraprofessionals' intervention at the neighborhood level is growth oriented, nonstigmatizing, and deemphasizes the "sick" label. Paraprofessionals of similar origins (i.e., ethnic and economic) have been found to be more acceptable to people needing help.

Since 1971 we have been studying subjects who were admitted to our Adolescent Crisis Ward with drug abuse problems. We soon discovered that once the adolescents left the hospital they would not return for aftercare. We found that adolescents and their families were much more responsive to community workers of similar backgrounds and to counseling sessions held directly in the home. It became increasingly evident that there was a need for community-based paraprofessionals trained in an effective, short-term, highly structured method of family intervention. While awaiting funding on a proposal for grant support, we decided to run a pilot program in which we trained paraprofessionals to conduct behavioral family therapy in their own communities, directly in the homes of alcohol-abusing adolescents. This project also gave us the opportunity to evaluate training methods, instruments, and treatment outcome.

METHOD

Training Procedures

Ten paraprofessionals (5 men and 5 women; 8 Mexican-Americans and 2 blacks) were selected to participate in this pilot study. Criteria for selection included 1) affiliation with a community-based agency for at least 6 months, 2) recognition as a paraprofessional, 3) ethnicity similar to that of the community, and 4) experience with drug-related problems and family work. The paraprofessionals were trained as a group for over 6 months (2 to 6 hours per week). They attended weekly didactic and workshop sessions in which principles of learning theory and family contracting were presented. The paraprofessionals were required to read Becker's *Parents Are Teachers* (20) and to complete a programmed manual, Stumphauzer's *Principles of Behavior Therapy* (21), and other relevant materials. In addition, they observed behavior therapy with families conducted by professionals and then discussed the process. They also had an opportunity to view and discuss films on social learning theory principles and practices (22, 23). The paraprofessionals were supervised as a group and then individually as they picked up families for treatment.

Treatment Process

Once training manuals and didactic sessions were completed, each trainee was required to treat three families in order to complete his participation in the program. Although there was a standard format of treatment and evaluation, the weeks of treatment varied with each trainee and each case. The first phase of treatment (initial contact) consisted of the initial few meetings with either the adolescent or the parent; its goal was information gathering and the establishment of an informal contract to work together. In the second phase of treatment (assessment), problem behaviors were specified. A reinforcement survey was administered to determine what rewards might reasonably be used in the program and what reasonable punishments were available as sanctions. Ways of measuring the important behavior were selected (Daily Behavior Graphs and Cards) and usually measurement was begun immediately to determine baselines, i.e., levels of the behaviors *before* intervention (24, 25). Data on drug use, the family, and functioning in school (i.e., attendance, grades, and conduct) were gathered as premeasures.

The third phase (initial contract) followed Stuart's format of general agreement, specific privileges, specific responsibilities, and signatures (26). The first contract worked on a relatively simple problem so that the family and the paraprofessional could experience success in contracting in a brief time (reinforcement). During the fourth phase (adjustment of contracting), which comprised the major thrust of treatment, the family and the paraprofessional worked on major family problems such as drug abuse, gang activity, severe school problems, and family relationships. During this phase contracts were changed and adjusted as necessary. Often outside agencies (e.g., schools and probation departments) were included in the contracting to ensure a thorough program and success. Family sessions centered on improving the family interactions. They often focused on changing from heavy use of punishment for undesirable behavior to positive reinforcement and praise for desirable behavior. In the fifth phase (termination), the family and outside agencies were given practice at making and adjusting contracts with mini-

mal guidance. Termination was agreed upon by the family and the paraprofessional, but in many cases some informal contact was maintained. Data on drug use, the family, and functioning in school were again collected at the time of termination as postmeasures of treatment success.

RESULTS

Training

Throughout the didactic presentations attendance was relatively high; at least 80% of the paraprofessionals were present at any given session. Of the 10 paraprofessionals selected, all participated in the didactic sessions. At the time a first case was to be selected, 4 paraprofessionals dropped out. Of the 6 who remained, 4 completed training.

At the start of training all paraprofessionals took a 100-item test that measured general knowledge of behavior modification. Their initial scores were all low, with no more than 30 correct answers. After completing their training, 4 paraprofessionals took the test again; the results (60 to 90 correct answers) showed a considerable gain in knowledge. However, caution should be used in drawing anything but tentative conclusions from this small sample. These 4 paraprofessionals also completed a questionnaire on the value of the training. In general, they agreed that the didactic sessions and workshops were helpful in learning the principles and the behavioral family therapy process. While they felt that *Parents Are Teachers* (20) was useful, they rated *Principles Of Behavior Therapy* (21) higher as a training manual. All were very positive about the need for continuing the training program with other paraprofessionals in their respective communities.

Treatment

The paraprofessionals selected cases from their agency caseloads shortly after training started. Twelve families have been treated (8 Mexican-American and 4 black). All of the adolescents selected presented with problems related to alcohol or drug abuse, school, the law, and their families. Almost all of the adolescents treated were experiencing severe problems in school in addition to drug problems. Some were truant, some were failing, and some had behavior problems. Usually contracts were made initially among the paraprofessional, the adolescent, and the family. When there was a severe school problem, the school was often included directly in the contracting. Four adolescents were on probation, and this necessitated an additional level of contracting.

All 12 youngsters presented with severe family problems, many with incorrigible behavior (e.g., verbal and physical aggression, running away, curfew violations, and gang activity). This necessitated a series of contracts that shifted their focus as the family and paraprofessional made progress. At times the paraprofessional made an individual contract with the adolescent and then moved on to work out a family contract.

Case Report

This series of events is exemplified by the case of Chavo, a 12-year-old Mexican-American. The first contract was a 4-week individual contract at the community center between Chavo and the paraprofessional. In it Chavo agreed to meet daily with the paraprofessional at the center and to try to attend school and stay sober. Each day he did both, the paraprofessional agreed to spend time with him and give him 50 cents in spending money. During the first week Chavo attended school 1 day and stayed sober 3 days; by the fourth week he was attending school 5 days and staying sober all week. This information was verified by his family and school.

At that point a 4-week family contract was drawn up among Chavo, his mother, and the paraprofessional. Family quarrels and chores at home were one focus. Since Chavo was involved in a gang, the plan was to develop behavior incompatible with gang activity, i.e., doing more at school, spending more time at home, letting his mother know where he was, and spending more time at the community center. The contract stipulated that in order for Chavo to stay out Friday nights until midnight, he must tell his mother when and where he was going, call home periodically, and do chores each day. During the first week Chavo called home 6 days and performed the other duties every day; by the fourth week he was performing all duties every day.

DISCUSSION

This program appears to be a viable model for training paraprofessionals and subsequently for community intervention for a wide variety of family problems, including alcohol abuse. The paraprofessionals learned the principles of behavior modification and continue to use them in their community agencies. Some have begun teaching these principles to and sharing workshop materials with their colleagues, who now seek them out as good resources. A few have begun to use these principles in dealing with situations in their own families as well as in measuring and modifying their own behaviors (e.g., smoking, weight control, and work habits). In addition, paraprofessionals from other agencies have called and requested an opportunity to be trained. Attrition presented a difficult problem in the implementation of this project. In assessing it, we discovered that the following factors contributed to the loss of paraprofessionals:

1. Differential capacity to assimilate the principles of learning and methods of behavior therapy.
2. Differential ability to maintain this highly systematic approach to treatment, i.e., maintaining a schedule for the time of study and keeping notes, graphs, records, and the like.
3. Competition among the trainees was such that a few paraprofessionals showed substantially more motivation and success.
4. The initial agreement for participation in the program was too informal; we feel that a formal contract

was needed for commitment to training.

In this preliminary project we began to learn how to work effectively with Mexican-American and black families in the urban areas of Los Angeles. From the vantage point of a large medical center, we were unaware of the nuances of family life in these communities. Even the indigenous paraprofessionals, who were more attuned to community life, had much to learn. For example, from our experience it appears that the Mexican-American father has difficulty accepting a non-family member into his home even though that person has a similar ethnic background; Chavo's father was also reluctant to admit there were family problems and to accept advice. Contracting with black families seemed easier; they more readily accepted strangers in the home and took suggestions from someone outside the family. Both kinds of families experienced strong competition from peer groups and gangs in efforts to improve their adolescents' behavior. Two gratifying findings that demonstrate generalization were that parents began using contracting with their other children and teachers began using these methods with other students.

We are encouraged by our findings. This training provided a structured model for the paraprofessionals' interventions with families in their communities. With the specificity of behavioral contracting methods, useful and concrete tools were provided that paraprofessionals are capable of learning and applying. In addition, they continue to use what they have learned in their community centers. This pilot program offers a fruitful model for the continued training of community-based paraprofessionals in family behavior therapy with alcohol-abusing adolescents.

LETTERS TO THE EDITOR

Another Approach to Avoidance

SIR: Psychiatrists who are interested in the supervisory process cannot help but appreciate the contribution made by Marcia Kraft Goin, M.D., and Frank Kline, M.D., in "Countertransference: A Neglected Subject in Clinical Supervision" (January 1976 issue). However, I feel that the authors may have failed to recognize the sensitivity and perhaps the good judgment of the supervisors whom they were studying.

Countertransference is a very personal area for a resident and one about which the new resident is often quite defensive. I do not think it was "curious to observe this delicate handling of unspoken issues," as the authors noted. To the contrary, I suspect that since the supervisors had known the residents for eight months, they may have known what they were capable of handling at the time the tapes were made and in what manner. The indirect approach can be effective at times, especially in initially dealing with countertransference problems. At other times, relating the supervisor's experience in dealing with examples of countertransference may be especially helpful to the new therapist.

I find it striking that the authors did not seem to take into account the fact that the supervisory sessions were being videotaped. A discussion with the supervisors might have shown how much the video process itself and the resultant lack of confidentiality influenced their approach to countertransference in the sessions, as well as revealing other individual reasons. Perhaps the 50% of the supervisors who "neglected" the countertransference or those who directly avoided bringing in the residents' personal reactions were actually demonstrating a sensitivity to issues of confidentiality. If this were the case and the issues of countertransference were dealt with more openly when the camera was off, we might have a meaningful lesson that could be applied by the resident in dealing with patients' private data.

MICHAEL BLUMENFIELD, M.D.
Brooklyn, N.Y.

Dr. Goin Replies

SIR: I appreciate Dr. Blumenfield's thoughtful comments. It is certainly true that being recorded on videotape must have an inhibiting effect on a supervisor. We attempted to counteract this reaction as much as possible by videotaping all of the supervisors at least three times and then having them choose for study the tape that was most similar to their style when working without such an intrusion. Later discussions with the supervisors (we looked at each tape with the supervisor involved) showed that they did feel the sessions were representative of their usual meetings.

The fact that Dr. Blumenfield mentions the issue of confidentiality is indicative of the kind of inhibiting ideas with which the supervisor struggles. Talking about a resident's feelings and reactions to his/her patients need not lead to a revelation of intimate, confidential secrets. Often, residents believe that they should be without reactions or feelings toward their patients and that the emergence of countertransference means they have failed to be the perfect therapist. It is the naturalness of the supervisor in accepting and expecting reactions that frees residents from such a distortion. A supervisor's belief that such reactions cannot be openly talked about in a teaching session but rather belong to the confidentiality of therapy poses a dilemma for supervisor and resident.

MARCIA KRAFT GOIN, M.D.
Los Angeles, Calif.

A Question of Ethics

SIR: I am a lay person who subscribes to the *Journal*. I would like to describe a personal experience related to an aspect of psychiatric ethics that may interest those who read "Overview: Ethical Issues in Contemporary Psychiatry" by Fritz Redlich, M.D., and Richard F. Mollica, M.D. (February 1976 issue).

My mother was recently committed for treatment of paranoia. During the complicated legal process, she chose as an independent examiner a psychiatrist whom she had seen a few times in the previous three years. About two years before her commitment, I had written a letter to this psychiatrist, hoping to enlighten him about the situation in my parents' home and giving many details of my mother's behavior.

During his latest examination of my mother, he read her my letter. I realize he may have done it to convince her that others think she is ill, but it has caused me untold pain and forever deprived me of my mother's trust. He, in effect, threw me to the dogs.

NAME WITHHELD

"Equivalent" Doses in Medication Changes

SIR: We have been concerned with the tendency toward an almost routine use of increasingly high doses of antipsychotic agents (1) and have recently encountered a case that illustrates one acute complication of the rapid change from one agent to another at relatively high "equivalent" doses.

A 30-year-old man with an 8-year history of bipolar manic-depressive illness was admitted to a psychiatric hospital in an acute manic psychosis and was treated with up to 1500 mg/day of lithium carbonate (blood levels of 1.0–1.5 mEq/liter), 20 mg/day of haloperidol, and 2 mg/day of benztropine mesylate. The patient's mania partially improved, but his insomnia persisted. Haloperidol was discontinued on the 6th day of his hospitalization and chlorpromazine was started immediately at a dosage of 1200 mg/day. Over the next 72 hours, the patient's mental status worsened progressively and he became more agitated and aggressive. His thinking

became disorganized, with persecutory delusions, visual hallucinations, and referential thinking. His speech became dysarthric and incoherent. His pulse rate was 110 per minute, his pupils were 6 mm and poorly reactive to light, and his mouth was very dry. There was no fever. On the 10th day, chlorpromazine and benztropine were discontinued and the patient's apparently organic mental symptoms resolved gradually over the following 36 hours. The mania also continued to improve and the patient was discharged on the 21st day on 1200 mg/day of lithium carbonate.

This case represents the superimposition of an apparently organic mental syndrome in a case of mania. Various forms of combined toxic-functional psychosis are being recognized increasingly often (2). Many features of the mental status and physical findings in this case indicate that the mental syndrome included central anticholinergic toxicity (2), although lithium may have been a further contributory factor. This toxicity may reflect the combination of a small dose of benztropine with a large dose of chlorpromazine, which is about 48 times more potent than haloperidol as a blocker of central muscarinic receptors (3). It is commonly stated that the approximate clinical milligram equivalency of these two agents is 1–5 mg of haloperidol to each 100 mg of the phenothiazine (4); in the case we have reported, a ratio of 1.7:100 was used. However, this case shows that the milligram equivalency for antipsychotic effects need not correspond to that for acute toxic effects. Moreover, it illustrates the importance of time in the estimation of "equivalency" of different agents. That is, while it may be safe to change rapidly among dissimilar antipsychotic agents at low doses, antipsychotic medication change should be done more slowly and carefully at higher doses.

An Unfair Indictment of Behavior Therapies?

SIR: In his article "The Behavior Therapies: Therapeutic Breakthrough or Latest Fad?" (February 1976 issue), Arthur K. Shapiro, M.D., is critical of the APA task force report on behavior therapy (1). He takes issue with each of the nine points cited in the report as advantages of a behavioral approach to our field. I am sure that all members of the task force (myself included) would agree that many controversial issues raised by behavior therapy can be argued cogently from more than one point of view. Resolution of these issues will require much research, thought, and study. However, Dr. Shapiro's article did not deal with any of the issues adequately and will not add to the reader's understanding of them.

I will illustrate this with a single example. Dr. Shapiro takes issue with the report's thesis that "behavior therapy is applicable to both psychological and organic illnesses." He points out that behavior therapy techniques have been used to treat patients with Gilles de la Tourette's syndrome who would probably have been better treated with haloperidol. This of course may be true, and one can always find instances in which clinicians espousing a particular point of view have not used the treatment of choice for a particular patient. Patients with this syndrome are also sometimes treated by psychoanalytic psychotherapy, inappropriate drugs, and other means. However, this is no basis for the author's sweeping conclusion that behavioral techniques are not applicable to patients with "organic" illness. For example, one of the most clear and impressive applications of behavior therapy procedures is in helping the mentally retarded acquire self-help and social skills and generally improved adjustment (2). The same can be said of disorders such as chronic schizophrenia and infantile autism, which may indeed have their basis in neurophysiological or biochemical dysfunction. Of course, behavior therapy is not going to "cure" these conditions, but it may be very useful in maximizing functional capacity, facilitating rehabilitation, etc. (3). There is also a substantial literature on the use of behavior therapy techniques in treating some of the classical "psychosomatic" disorders such as bronchial asthma and migraine headache. Finally, there is a whole biofeedback literature. Although this area has more promise than fulfillment at this time, some solid clinical research results have been published in the management and treatment of a wide range of "organic illness" (4).

For all the above reasons, Dr. Shapiro's statement that "this concept [that behavior therapy is applicable to organic illness] is untrue, adherence to it may be harmful and occasionally is lethal, and it is often pragmatically irrelevant" is far more oversimplified and polemical than anything in the task force report. This article does not add to our understanding of the uniqueness or the limitations of a behavioral approach in psychiatry.

JOHN PAUL BRADY, M.D.
Philadelphia, Pa.

Dr. Shapiro Replies

SIR: I was surprised by Dr. Brady's statement that my paper did not contribute to the reader's understanding of some of the complex issues involved in evaluating the efficacy of the behavior therapies.

My paper focused on and was limited to a critical examination of the advantages described in the APA task force report on behavior therapy. Some of the points Dr. Brady has raised should be considered in future discussions. However,

these and many other issues that were not discussed in the task force report were excluded from my critique, in part because of space limitations. It would serve no purpose to repeat the arguments I presented in the paper, and the reader is referred to it for his own evaluation.

The effectiveness of the behavior therapies in managing and improving the functioning of mentally retarded, schizophrenic, and other patients would be an important contribution. However, further discussion and clarification is needed to determine whether these activities should be classified as clinical therapies. However classified, their effectiveness must be documented by more than clinical impressions or poorly controlled studies that are so subject to placebo effects and type I errors. The consequences can be more serious in the therapy of organic conditions, and the use of such techniques should be subject to the same proof required by the Food and Drug Administration for pharmaceutical agents.

I believe that behavior therapists should not ignore these issues. Many prominent investigators concerned with issues of psychotherapeutic efficacy in general have questioned the adequacy of the controlled evidence in support of behavior therapies. In a recent study, the best and most comprehensive study I am aware of, Luborsky and associates (1) could not draw any conclusions from the controlled studies in the literature comparing behavior therapies with psychotherapy. They also thought it important to limit their review to studies involving patients with "pervasive personality and adjustment disorders that lead them to seek psychotherapy." Since this work was done at the University of Pennsylvania, and Dr. Brady is cited as assisting in its preparation, it is curious that he ignored these results and conclusions in his letter. Similar questions have been raised about the adequacy of the current evidence for the effectiveness of behavior therapies by Wolfe (2), Bergin (3), and many other prominent investigators.

The clinical use of biofeedback, mentioned in Dr. Brady's letter but excluded from my paper, is thought by Engel (4), Basmajian (5), Shapiro (6), and above all by Miller (7), who largely originated the concept, to have far outdistanced the evidence for its clinical effectiveness.

My paper was not meant to lightly dismiss the importance of the behavior therapies; otherwise I would not have taken the time to write it or to have hedged about the conclusions that should have been obvious from careful perusal.

Although the paper was meant to be somewhat polemical (I see nothing wrong with this in science), its main purpose was heuristic. I am sorry that Dr. Brady did not see it that way and disappointed that he found nothing of value in it—if that were true, it would be difficult to understand why it was published.

A Theory on "Psychogenic Polydipsia"

SIR: "Acute Psychosis, Increased Water Ingestion, and Inappropriate Antidiuretic Hormone Secretion" by Murray A. Raskind, M.D., and associates (September 1975 issue), sheds new light on so-called psychogenic diabetes insipidus.

I have encountered a variety of psychiatric conditions associated with polydipsia, but not always involving postmenopausal women (Dr. Raskind and associates' reports were of women over 50). One case was that of a 21-year-old woman seen within 2 months after an acute debut of undifferentiated schizophrenia with precipitating reactive factors. The patient was drinking 20–30 glasses of various fluids a day, but as soon as the neuroleptic treatment (150 mg/day of chlorpromazine and 20 mg/day of trifluoperazine orally) was instituted, the polydipsia disappeared.

Another patient was a 32-year-old man with a 6-year history of uninterrupted hospitalization for chronic schizophrenia followed by rehospitalization a year later for a paranoid relapse. The patient had been at home for the past few years despite his occasional aggressiveness, periodic severe regression, and persistently inappropriate behavior. He was drinking large quantities of tea, coffee, and soft drinks and vomiting soon after each ingestion. The patient denied any subjective thirst or dryness of mouth despite almost 10 years of continuous neuroleptic treatment.

A third polydipsic patient was a 40-year-old man who had been hospitalized following an ordeal caused by a shipwreck, rehospitalized, and for the past 8 years had functioned fairly well in a foster-home setting. Since his first hospitalization, he had been treated with large doses of neuroleptics. He suffered from unidentified seizures until adolescence and is mildly mentally retarded. His ingestion of large quantities of soft drinks led to bedwetting, presumably due to overflow incontinence. He displayed massive polyuria and nocturia and sweated profusely. Compulsive drinking and polyuria associated with progressively changing facial features suggestive of acromegaly prompted an investigation for pituitary tumor, with a negative result.

A fourth case was a 32-year-old man who was hospitalized 4 years ago for uncontrollable generalized seizures following a suicidal overdose of tranquilizers. A year later he was rehospitalized for a depressive episode, but he has been well controlled with anticonvulsants (120 mg of phenobarbital and 200 mg of diphenylhydantoin) and 30 mg of clorazepate dipotassium daily since. This patient habitually drank up to 50 cups of coffee a day.

In none of these cases has the hypothesis of inappropriate ADH secretion been tested.

I recall another case, that of a premenopausal woman in her early forties who was hospitalized for reactive depression with considerable anxiety and restlessness following a negative medical investigation of polydipsia. She had a vague history of head trauma many years before the onset of dryness of mouth that prompted her to drink up to a gallon of water daily. The diagnosis of Sjogren's syndrome was considered at some point but was eventually ruled out.

Head trauma as a factor occasionally precipitating

Schwartz-Bartter syndrome has been suggested by some (1). Caffeinism appears to be a related phenomenon in which the diuretic effect common to all methylxanthines triggers a vicious cycle of improper water balance. Heightened sympathetic tonus and adrenalinemia, presumably accompanying anxiety spells and chronic tension, probably fall into the same category. Drug-induced (anticholinergic) dryness of mouth may prompt excessive fluid ingestion, as does xerostomia associated with anxiety and depression through autonomic mechanisms. Pseudodysphagia experienced occasionally with globus hystericus is likely to induce repeated drinking to overcome the oropharyngeal spasm. A variety of other factors, from physical conditions of the environment to cultural phenomena, contribute to a faulty control of water balance on various levels and through various mechanisms.

I wonder how many cases of the heterogenous and heretofore obscure "psychogenic polydipsia" would be found to be related to inappropriate ADH secretion, if the hypothesis were tested properly.

"Something More"

SIR: We found "History and Analysis of a Leaderless Group of Professional Therapists" by Winslow Hunt, M.D., and Amnon Issacharoff, M.D. (November 1975 issue), especially stimulating and moving because of our own experience in a leaderless couples group of psychotherapists and their spouses that began four years ago (1). The authors' descriptions were very candid and vivid, but we disagree with their implied conclusion that the failure of the group lay in its leaderlessness. It is our impression that the dissolution of the group was related to a failure to confront and work through the fundamental theme that brought the members together initially, i.e., the ennui in their personal and professional lives.

The overt reason expressed for the creation of the group was to discuss experiences and problems in group therapy work, but the covert emotional agenda appeared to be concerned with alienation from self and significant others. In fact, the authors noted that individual members were searching for solutions to this problem in various professional workshops and therapies. The initial task, however, dealt with an area of their lives in which they felt gratified and complete—psychotherapy. Not surprisingly, the first task was accomplished satisfactorily and gave way to a new focus, the process of the group. It seems to us that this new focus was also off the mark. The next period of the group came closer to the primary agenda and was an "idyllic time." The group became a place where members could bring their anxieties and confusions and find support. Had the group members been more in touch with and open about their reasons for being there, they might have continued as a support group, and the limits of the gratifying potential of others within the group itself might have become clarified. It appears that the searching continued, however, and the group attempted to mobilize a therapy focus to achieve what seems to us to be gratification of the ungratifiable; when they asked for "more," hostility and dissension appeared. We agree with the authors' speculation that the group members may have "simply wanted a closer, more supportive community than any of them had." The decision to end the group appeared to be an angry response to a lack of gratification rather than frustration over the failure to find a group leader.

The proposition that a group leader might have been that "something more" seems to be an extension of the expectation that some higher power—if not the group itself, then a group leader—could provide complete gratification, or at least a release from the ennui of life.

It has been our experience that a leaderless group of professionals can be a viable reference group for professional and personal anxieties and that when spouses and children are integrated into the group experience a type of extended family is formed that provides a buffer for the alienation hazards of the profession. Perhaps if the members of the group described in the article had attempted to integrate into the group experience "the intimate relationships that really mattered most to them—with wives, lovers, and children" they *could* have had something more. Even here, however, group members have to adapt to the frustrating experience of not getting all they want.

FRAN PEPITONE-ROCKWELL, PH.D.
Sacramento, Calif.

Drs. Hunt and Issacharoff Reply

SIR: We did not wish to imply that every group needs a leader who is so labeled. Most groups need a leader in fact but not necessarily in name. One of the papers referred to in our article described a group that lasted 15 years without a formal leader. However, when the authors examined the group process in retrospect, they discovered that one person *had* served a leadership function.

We do not think that the leadership function need be embodied in any one individual—it can move from person to person or be contained in the relationship of the group to an outside institution or idea. What we are saying is really very simple. Anything that is going somewhere needs a steering mechanism. This seems too obvious to require emphasis, but we suggest that any leaderless group make sure that its steering mechanism, whatever it may be, is intact and working.

Dr. Folkins and associates comment that "dissolution of the group was related to a failure to confront and work through . . . the ennui in their personal and professional lives." Our failure to work certain things through was, we hope, clearly acknowledged in the article; the issue is why this was the case. Dr. Folkins and associates seem to hold what one might call the "better people theory" to explain the difference between our two groups. Their group worked and ours did not because the members of their group tried harder or were more honest or less demanding than the mem-

bers of our group. We think that this theory has limited explanatory power. In thinking about our own experience, we attempted to go beyond the admitted limitations and faults of the group members as individuals and to explain what happened in a more structural sense by exploring the setting, form, and process of the group. This led us to the formulation that relative to the task we needed to perform (to change the basic contract and raison d'être of the group), we did not have a leadership function of sufficient power.

At no point do Dr. Folkins and associates refer to their group as a therapy group. We think it is significant that they use the terms "reference group" or "support group." Their group may very well be functioning well as a support group, i.e., a group in which the positive and binding emotions are articulated and expressed and in which there is repression (and wisely so) of envy, rivalry, narcissistic rage, and other hostile emotions that exist in all human beings and that tend to break up the bonds between individuals if expressed. Our group members were ambitious in wanting to become a true therapy group, i.e., one that also dealt in depth with the negative emotions. Would that we had settled for being a support group!

Dr. Folkins and associates refer to our statement that "group members were without exception very committed to the practice of psychotherapy and it was a major source of gratification, albeit one that most took for granted." In a personal communication, Dr. Leon Balter has pointed out that this statement may be a defensive denial of an unresolved group issue. He called to our attention the universality and significance in the lives of all psychotherapists of guilt, both justified and irrational, for injuring their patients or for not helping them enough. The wish to deal with this guilt may have been a more important part of the secret agenda of the group than we recognized, and our failure to deal with it may have been important in the life of the group. This suggests that the group members may have projected that guilt onto the leader whom they refused to create or find in their own consciences (i.e., that if we ever found a leader he would take us to task for our failures with patients).

Since our article was published, many psychotherapists have spoken to us about their own experiences with small, informal, emotionally supportive groups of colleagues. It has become clear to us that intensive psychotherapy places emotional demands on its practitioners such that they have on almost universal need for a supportive group beyond what is provided by the formal institutions of the profession. This need has probably been experienced and responded to since the very creation of our calling when in 1902 Freud started his psychological Wednesday evenings.

Capgras Syndrome: A Case Involving Violence

SIR: There has been an increase recently in reports of Capgras syndrome, including several cases in men (1–4). The following case, although not entirely classic, is interesting in that it involves a serious violent episode and also illustrates the dynamics of the syndrome.

A 32-year-old man got into difficulty at work and returned home to his parents, who had exerted pressure on him regarding his job. His parents had also criticized his fiancée, which made him feel inadequate. He became convinced that his parents were not his real parents but rather had stolen him from his real mother when he was young. He remembered his mother once stating angrily that she did not want him as her son and that he was not her son. He felt that his parents had been replaced by machinelike beings who had been suppressing him all his life.

As a result of his behavior, his parents made an unsuccessful attempt to place him in a hospital outside his catchment area. The patient thought he had been evaluated at the hospital by a homosexual attendant and therefore believed that his parents were trying to make him into a homosexual. Upon returning home the night of this evaluation, he went after his parents with a meat cleaver and seriously injured his mother. He believed that this act would free him from these impostor parents and remained convinced of this for some time after the event.

This episode in a paranoid schizophrenic man illustrates how homosexual panic and unacceptable anger toward his mother were dealt with by the delusion that his parents had been replaced by impostors. Tragically, this delusion caused him to seriously injure his mother. This case illustrates the development of a form of Capgras syndrome that enabled a man to perform an uncharacteristic violent act.

Treating Depression in Patients with Cardiovascular Problems

SIR: A basic problem with clinical psychopharmacology of which I have become acutely aware in reviewing some of the literature is the problem of endogenous or psychotic severe depression in patients who have cardiovascular problems, specifically arrhythmias or atherosclerotic heart disease with arrhythmias. The problem is often one of deciding which illness one should treat, the cardiovascular problem or the depression. Unfortunately, we are often unable to make a clear decision because the two conditions are equally life threatening. It seems to me that the most obvious problem involved in giving psychotropic medications for depression is adrenergic stimulation, which clearly has detrimental effects on cardiac arrhythmias and hypertension. I would like to share a clinical vignette of such a problem that I encountered when I was a psychiatric consultant to the renal unit at an Army medical center.

The patient was a 58-year-old man who was suffering from chronic renal failure, was on chronic hemodialysis, and also had underlying atherosclerotic heart disease with irregularly occurring episodes of sinus tachycardia. He was hospitalized because of complications in maintaining his diet and regular dialysis. Because of the underlying serious depression, he had become agitated and more depressed in the hospital and

began expressing strong suicidal ideation. Despite supportive psychotherapy, his condition was not improving and it was decided that some form of antidepressant medication had to be administered (with all his other problems, ECT was considered to be contraindicated). Before my arrival on the ward as consultant, the patient was started on very low doses of amitriptyline; after two days, he suffered a cardiac arrest. He was resuscitated but continued to have evidence of cardiovascular problems. He was still quite depressed, had all the usual vegetative signs of depression, including insomnia, agitation, early morning awakening, refusal to eat, weight loss, and serious feelings of guilt and worthlessness.

I reached back into my medical experience to try to come up with a solution. The attending internist and I both agreed that the patient definitely needed treatment for his depression because he was clearly capable of killing himself. Therefore, we decided that whatever novel approach we might take with this problem would be justifiable. Upon obtaining informed consent from both him and his spouse, we placed him on 10 mg of propranolol four times a day and after 24 hours started him on imipramine in very low doses (10 mg four times a day) and gradually worked our way up to 75 mg of imipramine and approximately 40 to 59 mg of propranolol a day. After approximately 10 days on this regimen, the patient's mood began to improve markedly, his cardiac arrhythmia was in good control, his appetite returned, and he was sleeping well. After approximately 20 days, his depression was in good remission and his cardiac status was also stable. He was subsequently able to be discharged from the hospital, was much more cooperative in his diet and hemodialysis program, and was followed up by the psychiatric service with supportive psychotherapy and medication regulation.

Although there are many theoretical objections to the concept of using a tricyclic and a β-blocking agent such as propranolol (i.e., the resultant excess α-adrenergic stimulation that might result), it was my experience that this combination is quite safe and may give us the margin of safety we need to treat seriously depressed patients with cardiac problems who otherwise might be beyond our reach.

Killeen, Tex.

A Fair Comparison?

SIR: I read "Comparison of Two Five-Year Follow-Up Studies: 1947 to 1952 and 1967 to 1972" by J. Sanbourne Bockoven, M.D., and Harry C. Solomon, M.D. (August 1975 issue), with concern because the authors did not seem to have provided any evidence to support their conclusions. It should go without saying that one must compare like with like if a comparison is to have any validity. In fact, the groups the authors described differ significantly in practically every area mentioned.

First, the Boston Psychopathic Hospital patients were very selectively derived from a large and widespread population, while the Solomon Mental Health Center patients came from a compact urban sector and were presumably much more representative of the mentally ill in their area. Second, the relative proportions of patients in the two groups who had or had not had a previous admission are entirely different. Third, the relative proportions in the various diagnostic categories are also quite different. I also presume (although we are not told enough about this point) that the Solomon Center is rather more representative of mental health facilities in the United States than the Boston Psychopathic Hospital, an exceptionally well-staffed postgraduate teaching hospital.

All of these differences are in addition to those specifically mentioned by the authors, and it is really not accurate to state that the two groups were "random samplings of admissions from their respective communities." Clearly, they were anything but that.

These deficiencies of method are most serious in relation to the authors' conclusion that "psychotropic drugs may not be indispensable to the success of community-based mental health services and that their extended use in aftercare may prolong the social dependence of many discharged patients."

The Solomon Center patients included 33 with "miscellaneous" diagnoses (personality disorder, psychoneurosis, etc.) compared with 6 patients so categorized in the Boston Psychopathic Hospital Group. Obviously, the responses of these patients to psychotropic medication will be considerably different from those of patients with a diagnosis of schizophrenia or affective psychosis, and the overall experience of the two groups will vary correspondingly.

This point concerns me particularly because I have been engaged for the past nine years in examining the effect of long-acting fluphenazine medication in schizophrenics derived from a defined population of 125,000 recorded by the Salford Psychiatric Case Register (1) and treated by a community-based psychiatric service. The mirror-image method uses the patients as their own controls and the sample now consists of 252 patients, all of whom had had at least one admission before the treatment regime was commenced. The minimum follow-up is one year. (The methodology of this study has been described more fully elsewhere [2].) This sample had a total hospitalization of 14,889 days before the injection regime was started, compared with 4,143 days after the injection treatment began, other significant factors being constant. Treatment is currently maintained in all cases.

Hospitalization is a very imperfect measure of morbidity, but if it is to be used at all, it cannot support the view of Drs. Bockoven and Solomon toward psychotropic drugs in the community management of schizophrenia.

Drs. Bockoven and Solomon Reply

SIR: We are especially pleased by the interest evoked by our article. Dr. Freeman's letter merits particular comment. Our point in writing the paper was to present evidence that the older and still persisting pessimistic psychiatric view of mental illness is unwarranted and unacceptable. We do not consider the details of our statistical approach to be the important issue. We do consider 100 unselected consecutive ad-

missions to be reasonably representative of admissions to the two facilities. Indeed, we regard the rather similar outcomes of the two studies to be of added interest precisely because of the differences between two samples of people who shared the factor of being regarded as disturbed enough to be admitted to a mental hospital.

We feel that it is extremely important that studies similar to ours be done at many different locations in the world. It is of special importance to conduct studies designed to learn why some illnesses are long term and others are not.

In regard to psychotropic drugs, we find it interesting and worthy of note that the outcome of the two programs was so similar, given that one used such drugs extensively and the other did not use them at all.

HARRY C. SOLOMON, M.D.
Lowell, Mass.

Homeopathic Dosage in Maintenance Therapy

SIR: In "Overview: Maintenance Therapy in Psychiatry: I. Schizophrenia," John M. Davis, M.D., emphasized the value of antipsychotic maintenance medication in the prevention of relapse. He also reviewed the article by Paul and associates (1) and said that many of the patients in their study were receiving homeopathic doses of neuroleptics, so that in effect the study was comparing ineffective doses with no drugs. If one examines the original study by Paul and associates, one will realize that a basic, if not the most basic, point of that study was that many patients *are* in fact treated with homeopathic doses, with the prescribing physician believing that he is preventing a relapse.

I think Dr. Davis should reemphasize the point that there are placebo doses of antipsychotics that have *no* beneficial effect on behavior or on relapse. This is particularly important in light of the side effects (cataracts, tardive dyskinesia, etc.) that can occur even with low doses of antipsychotics. What should be stressed is that the relapse rate for schizophrenics is high and very long-term follow-up is therefore the rule, but within that framework, few or no homeopathic dosages should be used.

REFERENCE

1. Paul GL, Tobias LL, Holly BL: Maintenance psychotropic drugs in the presence of active treatment programs. Arch Gen Psychiatry 27:106–115, 1972

GEORGE MIDDLEKAUFF, M.D., PH.D.
Chicago, Ill.

Dr. Davis Replies

SIR: I agree with Dr. Middlekauff that some patients treated with homeopathic doses are essentially receiving a placebo dose and the drug should be completely discontinued to avoid long-term side effects. I provided evidence in support of this opinion in part I of my overview (December 1975 issue, pp 1242–1243), particularly in table 2. The results of the Paul and associates study, although consistent with this, do not provide compelling support for it. Some of the patients in their study were treated with tricyclic antidepressants, which may exacerbate schizophrenia and in any case would not have any prophylactic properties. Because these patients were not eliminated from the study, confounding effects of the tricyclics make the results uninterpretable as presented. Most importantly, however, these authors used the wrong statistic. Their analysis of the data was confounded in the classical sense. Without the proper statistics, it is impossible to interpret their findings.

Although I do agree that some patients treated with homeopathic doses probably do not need the medication and it probably should be discontinued entirely, I have also seen patients who do experience good prophylactic effects on what seem to be very low doses of neuroleptics and who do predictably relapse when these doses are discontinued entirely. Thus, I do not feel that *all* patients on low doses are being treated with placebo doses, but I suspect that some are. As I stated in my overview, I feel that medication should be reduced from time to time for chronic patients, and sometimes complete discontinuance is called for in order to determine empirically whether or not they still need maintenance medication.

JOHN M. DAVIS, M.D.
Chicago, Ill.

Maintenance Therapy Guidelines

SIR: I wish that John Davis, M.D., in his article "Maintenance Therapy in Psychiatry: I. Schizophrenia" (December 1975 issue), had emphasized the fact that many patients do not need maintenance therapy. He does mention this in several places, but it is buried in the text of his excellent paper rather than being prominently displayed.

It is well known that neuroleptics can cause permanent and serious side effects, especially tardive dyskinesia and ophthalmological problems. The data that Dr. Davis presented show that anywhere from 0 to 82% of the patients studied had not relapsed by the end of the study period. Investigations that have covered an extended period of time (e.g., 1) have shown that some patients may have one psychotic episode and never relapse.

Because I am loath to take the risk of inducing these long-term side effects unnecessarily, I attempt to predict whether or not the individual is likely to experience another psychotic episode. Unfortunately, there is no sure way to do this. Empirically, I have found that the only predictor I can use is the presence of previous psychotic episodes.

With this in mind, I use the following protocol for maintenance treatment of schizophrenics. If the psychotic episode was the first for the patient, I continue neuroleptics for nine months following cessation of psychotic symptoms and then gradually discontinue the dose, followed by 6–12 months of observation. If it is the patient's second psychotic episode, I follow the same procedure, but I use 2 years of medication and a follow-up observation period that varies depending upon the symptom-free interval, with a minimum period of 12–18 months. If the patient has had three or more psychotic episodes, I continue him on medication for life, with a dosage reduction to the minimum necessary to prevent psychotic symptoms. In such long-term maintenance, I institute drug holidays, at first over weekends. I use a similar protocol with patients who have had major depressive episodes and are on tricyclic antidepressants.

I would like to emphasize that I have only impressionistic evidence that this protocol works. I would certainly appreciate any comments other practitioners may have about this protocol or about their usual drug maintenance practices.

KENNETH SOLOMON, M.D.
Department of Psychiatry
Albany Medical College
Union University
Albany, N.Y. 12208

Dr. Davis Replies

SIR: My suggestions as to the indications for maintenance therapy are quite similar to Dr. Solomon's and were discussed in my section on clinical issues, which is followed by a lengthy section on prevention of long-term side effects. I said essentially that I do not advocate maintenance medication in the first episode of reactive schizophrenia and would only use it when there is some indication that the patient suffers from a chronic relapsing disease. I differ somewhat from Dr. Solomon in that I do not advocate treating patients for life but rather feel that patients should undergo trials of lower doses. If they do not relapse, a trial of complete discontinuance of drugs is in order to determine empirically whether they in fact need to continue medication. This can be done without great difficulty in the hospital, but on an outpatient basis one sometimes has to carefully weigh risks and benefits. Dr. Solomon's rules for discontinuance seem reasonable. In my presentation I reviewed the general principles behind discontinuance rather than providing a specific prescription, and I pointed out that I do favor individualization of the treatment options.

JOHN M. DAVIS, M.D.
Chicago, Ill.

A Clarification

SIR: The recent overviews on maintenance therapy in psychiatry by John M. Davis, M.D. (December 1975 and January 1976 issues) provided an extremely valuable synthesis of widely scattered data on lithium carbonate, antidepressants, phenothiazines, and related agents. Dr. Davis' integration of these data into a comprehensible whole is of immense value to the practicing psychiatrist who treats chronic or recurring psychiatric disorders.

However, part II, which deals with affective disorders, contains what I believe to be an error. Dr. Davis states,

> The combined probability that lithium has a prophylactic effect in comparison with placebo or a previous treatment is 6×10^{-11} for recurrent depressive disorders. In a similar manner one can combine the probabilities from the various studies for bipolar disease: the probability that lithium prevents recurrence of a bipolar disease in comparison with no lithium is 3×10^{-24}.

While the context makes it clear that Dr. Davis is speaking of the probability that the results observed in all of the studies summarized in table 2 would occur *by chance alone*, the statement as it stands suggests that there is a minuscule probability that lithium has any prophylactic effect. In the interest of exactness (which otherwise characterizes these fine articles), I believe the statement should be amended to reflect its actual meaning.

DUGALD D. CHISHOLM, M.D.
Los Angeles, Calif.

Dr. Davis Replies

SIR: I agree that adding the phrase "by chance alone" would have been a more explicit expression of the concept intended.

JOHN M. DAVIS, M.D.
Chicago, Ill.

ECT as Maintenance Therapy in Schizophrenia

SIR: "Overview: Maintenance Therapy in Psychiatry: I. Schizophrenia" by John M. Davis, M.D. (December 1975 issue) is a well-done review of the literature. However, the article fails to mention convulsive therapy as a form of maintenance therapy for schizophrenia.

Convulsive therapy was first used to treat schizophrenia but has since been used predominantly in the treatment of affective disorders because they are more exquisitely sensitive to its therapeutic action. Kalinowsky (1) has reported a remission rate of 80.4% in acute schizophrenic episodes of less than six months' duration. He found a relapse rate of only 11% in six months to two years following discharge. The usual frequency of maintenance ECT treatment for schizophrenia is once a month (1).

We have been treating a number of schizophrenic patients with ECT to control their symptoms. After they have responded to a course of ECT, these patients are followed closely in individual therapy. Those who develop early symptoms signifying the beginning of a relapse are given ECT on an outpatient basis and have had amelioration and/or disappearance of their symptoms. This regimen has aborted psychotic episodes and obviated the need for hospitalization and maintenance medication; it also confirms Kalinowsky's observation (1) that patients who respond initially to ECT usually respond to it again when so treated for a relapse.

There is another reason for considering ECT for the treatment of schizophrenic disorders—the risk of tardive dyskinesia as a side effect of neuroleptics, an issue Dr. Davis addressed. Most cases that have been reported are in older females given large doses of neuroleptics, and they are irreversible. There has been an increasing number of reports about younger people who have been taking this medication for less than six months (2). We have recently seen two such patients. Both were women under 40, and one had been taking the medication for less than one month prior to developing dyskinesia. Neuroleptics are far from innocent drugs. A patient successfully treated with ECT is not in danger of developing tardive dyskinesia.

There are many other situations where neuroleptics are

contraindicated or carry strong reservations, e.g., during pregnancy, when a patient is concurrently taking certain antihypertensive medications, or when there is evidence of hepatic impairment, renal insufficiency, or cardiovascular disease (3). In all of these situations, ECT would be safer than neuroleptics.

We feel that ECT as a form of therapy in schizophrenia has been neglected not only in Dr. Davis' overview but also by practitioners in general. With the introduction of the phenothiazines in the 1950s, there was a profound decrease in the use of ECT for the treatment of schizophrenia. We would like to suggest that discarding the use of ECT and unequivocally embracing the phenothiazines was premature and unwarranted.

Encephalopathy and Psychiatric Diagnosis

SIR: In "Viral Encephalopathy Mimicking Functional Psychosis" (February 1976 issue), Lawrence G. Wilson, M.D., cautioned psychiatrists against accepting a diagnosis of schizophrenia "for an acutely psychotic patient without careful consideration of alternative explanations." He reports on three patients initially diagnosed as having catatonic schizophrenia who were subsequently found to be suffering from an organic psychosis.

I should like to caution psychiatrists to be wary of accepting a diagnosis of "viral encephalopathy" for patients in whom neither the infectious nature of the process nor its viral etiology has been firmly established lest "viral encephalopathy" become nothing more than a cliché concealing our ignorance of acute encephalopathies of unknown causes. The three patients Dr. Wilson described undoubtedly suffered serious organic brain disease, but its viral or infectious nature remains unproved.

The patient in case 1 became febrile only after choking and aspiration and developed spinal fluid pleocytosis only after a bloody spinal tap, gram-negative sepsis, and ECT. The rise in serum antibody titer for herpes simplex virus may have reflected only activation of a latent process. The second patient had a negative brain biopsy pathologically and negative viral cultures of brain matter at a point in the disease process when a positive culture might have been expected. Furthermore, if my interpretation of the case report is correct, the patient showed elevated cerebrospinal fluid (CSF) cells (to a maximum of 10) only after the brain biopsy. The third patient became febrile only after developing pneumonia and had increased CSF cells (to a maximum of 8) only after status epilepticus. Thus in none of these cases was a viral or infectious origin clearly established.

Certainly the history and clinical picture of each of these patients is compatible with a diagnosis of viral encephalopathy, and if one is compelled to assign a diagnosis, this choice should not be condemned. To accept this diagnosis without firm evidence, however, seems similar to accepting the diagnosis of schizophrenia without considering alternatives. It precludes interest in an investigation of acute encephalopathic processes of unknown cause. In this instance, I would like to join Dr. Wilson in suggesting that we expand the horizons of our inquiries.

CHARLES E. WELLS, M.D.
Nashville, Tenn.

SIR: Dr. Wilson's article created much interest from our staff because of a similar case on our service. As with Dr. Wilson's case, our patient presented with mental status findings of acute schizophrenia and without laboratory evidence of encephalopathy. Our patient did have a subtle defect in naming common objects, but this was initially attributed to anxiety. At no time did he exhibit fever. Two EEGs, skull films, and brain scan were normal. Lumbar puncture on the 10th hospital day demonstrated opening pressure of 170 mm of water with 2 red blood cells, 2 polymorphonuclear leukocytes, and 4 lymphocytes. Protein and glucose were normal. The patient's acute psychosis gradually disappeared over 3 weeks. His nominal aphasia persisted and became more obvious as the "thought disorder" ended. After 5 weeks of hospitalization, all clinical and laboratory tests were completely normal and the patient returned to military duty.

Such cases appear to be unusual presentations of encephalitis—but could these illnesses represent one subset of etiologies for acute schizophreniform psychoses? Certainly, more patients admitted with acute psychoses should receive spinal fluid examinations and viral serologic studies to rule out encephalopathy.

LT. CDR. ROBERT MALCOLM, MC, USN
Charleston, S.C.

Dr. Wilson Replies

SIR: Dr. Wells raises valid objections against presuming that for which we have minimal evidence. Definitive evidence of a viral or infectious etiology is lacking in my cases 2 and 3 and is only suggestive in case 1. We had close collaboration with our neurology colleagues on all 3 of these cases and relied on their clinical experience to a very large degree. When they said, "These cases are very similar to proven cases of herpes encephalitis that we have seen, although we lack definite evidence," we accepted their presumptive clinical diagnosis. I agree with Dr. Wells that "encephalopathy of unknown cause" or "*presumed* viral encephalitis" would have been a more accurate description of the cases and a more accurate title for the paper.

Dr. Wells notes that in cases 1 and 3 small numbers of lymphocytes appeared in the spinal fluid only after the occurrence of rather severe systemic illness, a bloody spinal tap, ECT, and status epilepticus. However, in case 2, Dr. Wells interprets the small elevation of CSF lymphocytes to 10 as occurring only after brain biopsy had been performed. Although the temporal sequence is somewhat unclear in the

case report, this finding occurred on the 10th *total* hospital day, which was the 3rd day after referral to the university hospital and preceded the brain biopsy.

I hope, like Dr. Wells, that more sophisticated serologic and other laboratory studies will enable these very complex cases to be more accurately and specifically diagnosed in the future. From the perspective of the psychiatrist, however, whether the specific diagnosis is known or not, the general problem of an organic and possibly infectious brain disease "masquerading" as a functional psychosis raises very difficult questions in clinical management.

Dr. Malcolm's letter suggests that acute organic psychosis of undetermined etiology may be much more common than we had previously believed. Undoubtedly, many cases similar to his have been signed out as "acute schizophrenic episode, in remission" because discrete aphasias or mild disorientation were not searched for and therefore not discovered. A Canadian investigator (1) doing postmortem brain stem examinations of mental health patients and general hospital control subjects recently reported some related findings. Unexpectedly, he found glial nodules and perivascular infiltration—which he felt were suggestive of an encephalitic process—in six of seven patients diagnosed as schizophrenic but in none of the controls. As Pincus and Tucker (2) pointed out, more and more of these "schizophreniform" psychoses will probably be found not to be "functional" at all, but instead of very definite organic etiology.

LAWRENCE G. WILSON, M.D.
Seattle, Wash.

A Methodological Question

SIR: In "Antiparkinsonian Agents and Fluphenazine Decanoate" (January 1976 issue) Scott Idzorek, M.D., discussed 19 patients receiving fluphenazine decanoate, presented data on incidence and severity of extrapyramidal symptoms, and drew conclusions about the use of antiparkinsonian agents and the comparative value of fluphenazine decanoate and enanthate preparations. It is difficult to understand how the data yield these conclusions, since the patients were initially unmatched and there are no data to suggest that they were comparable to the patients in the cited study of Chien and associates (1). Specifically, the patients "fell into three groups with respect to the use of antiparkinsonian agents," receiving the antiparkinsonian drug daily, irregularly, or not at all. The three groups are compared, but the critical question of how patients gained entry into these groups is not clarified. It seems that they were not randomly assigned, yet clinical criteria for use of an antiparkinsonian agent are not described. Furthermore, if patients "fell" into their respective groups because of clinical need, then they were preassigned (from the standpoint of this study) based on their susceptibility to extrapyramidal reactions.

It is somewhat puzzling that the uncontrolled data in this publication are considered novel, especially since there are a number of studies (some double-blind) that more adequately address the same question (2–6). A recent review (7) presented the possible pharmacological explanations for the differences between the enanthate and decanoate preparations of fluphenazine (8–10).

ALAN J. GELENBERG, M.D.
MICHAEL R. MANDEL, M.D.
Boston, Mass.

Dr. Idzorek Replies

SIR: The 19 patients in my study were referred to a fluphenazine clinic for the purpose of attempting to better control their psychotic symptoms. In general, these patients were characterized by a long history of schizophrenia, previous psychiatric hospitalizations, a history of not taking oral psychotropic medication as prescribed, and poor social adjustment. The primary concern was to treat each patient's psychotic condition; the collection of data on the incidence and severity of extrapyramidal symptoms was a secondary priority.

All patients were given fluphenazine decanoate in the lowest dosages necessary to control psychotic symptoms. Patients who were already receiving an antiparkinsonian agent when they were referred were initially kept on this medication; a portion of these patients were ultimately taken off the antiparkinsonian agent. Patients who were not receiving an antiparkinsonian agent at time of referral were not given one unless significant extrapyramidal symptoms developed.

After data were collected, it was noted that the patients could be divided with respect to the use of an antiparkinsonian agent into three groups—those who had used an antiparkinsonian agent daily, those who had not used an antiparkinsonian agent, and those who had used an antiparkinsonian agent during a portion of the study.

The results reported by Chien and associates (1) on patients receiving fluphenazine enanthate indicated a higher incidence and intensity of extrapyramidal symptoms than the results reported in my study. Although methodological differences make it impossible to directly compare our respective results, I feel that there are enough important similarities between the two studies to permit at least a general comparison. These similarities include the type of patient (chronically psychotic), the use of a depot fluphenazine medication on a periodic but regular basis, and a common rating scale to evaluate extrapyramidal symptoms.

I made no attempt in my article to explain the differences in the results of these two studies. Such a discussion would be a valuable topic for future communications.

Thiothixene and the Postpsychotic Depressive Syndrome

SIR: I read "An Investigation of the Postpsychotic Depressive Syndrome" by Thomas H. McGlashan, M.D., and William T. Carpenter, Jr., M.D. (January 1976 issue) with particular interest because I recently treated a patient who presented a classical picture of this syndrome. She was admitted to the hospital in a florid psychotic state of sudden onset. She was grossly delusional, thinking that she was possessed by the devil and otherwise persecuted. She had auditory hallucinations, incoherent speech, marked thought disorder, severe agitation, and incongruent affect. She was given 30–40 mg of haloperidol daily with rather dramatic results. Her psychotic symptoms were quickly brought under control, and within 10 days she was practically symptom-free except for mild depression. She was discharged on 20 mg/day of haloperidol plus 6 mg of benztropine mesylate.

Within a few days, however, her depression worsened, she was crying for no apparent reason, and she became preoccupied with suicidal ideas. She felt hopeless and decided to take an overdose. At this point, she was rehospitalized, and her medication was changed to 40 mg of thiothixene daily. She responded very well to the change of medications—her symptoms of depression gradually improved, she was no longer suicidal, her spirits improved considerably, and she developed an optimistic outlook. She was discharged from the hospital in three weeks in very good remission—except for some anergia that persisted for a time, she was completely back to her normal self. Her thiothixene dosage was gradually reduced to 10 mg/day.

In view of the fairly well-documented antidepressant effects of thiothixene (e.g., 1, 2), I wonder if it could be regarded as the treatment of choice for postpsychotic depressive syndrome (PPD). It would also be interesting to see if thiothixene could be used as a preventive measure in the initial treatment of patients who seem likely to develop PPD.

V.F. OGNYANOV, M.D.
St. Louis, Mo.

Drs. McGlashan and Carpenter Reply

SIR: We were pleased with Dr. Ognyanov's interest in our article, and the case he presents certainly fits the postpsychotic depressive syndrome phenomenologically. On the basis of a single case, however, we feel it is difficult to conclude that any drug (in this case thiothixene) can be regarded as the treatment of choice in PPD.

In a review of the literature on PPD (1), we found only one systematic study of its treatment with drugs (tricyclic antidepressants and phenothiazines) (2); the results were inconclusive at best. Few data are available to guide the clinician as to the preferred pharmocologic treatment for PPD. In the face of depression during the resolving phase of psychosis, Detre and Jarecki (3), Klein and Davis (4), and Ayd (5) suggest that the addition of a tricyclic antidepressant to the patient's phenothiazine regimen may be useful in selected cases.

It is also important to remember that depression following psychosis may be the *result* of drug treatment during the acute phase, as was suggested by our study and several others in the literature (5–10). It is possible, for example, that the depression of Dr. Ognyanov's patient was somehow linked to the use of haloperidol. If so, her recovery from depression may have resulted from the discontinuance of this drug rather than the addition of thiothixene.

Clearly, an attempt should be made to estimate the origin as well as the severity of any case of PPD. Such an exercise in differential diagnosis often clarifies the necessary therapeutic action. Cases that seem to represent a side effect of neuroleptic medication may be treated by cessation of drugs, change of medication, or the addition of antiparkinsonian agents. Cases that are prolonged and closely mimic a picture of endogenous depression may respond to the addition of an antidepressant drug. Finally, many cases of "depression" following psychosis represent an appropriate—and adaptive—grief response to the personal crisis of psychosis. For such patients, somatic treatment may actually be antitherapeutic (11). Supportive or expressive psychotherapy without drugs would be the optimal approach in such cases.

At the present state of our knowledge, each patient with PPD must be evaluated individually according to his needs and the physician's clinical judgment. General statements regarding the most efficacious treatment approach to PPD, however, must come from further systematic investigations.

"Postmanic Traumatic Neurosis"

SIR: I read with great interest "An Investigation of the Postpsychotic Depressive Syndrome" by Drs. McGlashan and Carpenter and the "Discussion" by Joel Kotin, M.D. (January 1976 issue). I have described a similar condition following mania (1) that I see as a traumatic neurosis. I recommended treatment through psychotherapy.

Treatment of the traumatic neuroses of bipolar illness cannot burden the patient with the responsibility for his illness, which is genetically determined and biochemically mediated, unless it is hypothesized that intrapsychic or interpersonal stress precipitated the illness. Dr. Kotin holds that the patient must accept the burden of responsibility in schizophrenia. I know of no scientific evidence that the cause of schizophrenia is any more the patient's responsibility than that of bipolar illness.

Many of my patients with postmanic traumatic neurosis accused me of trying to make them into an "outsider" (2) because I did not give them hope that they could change their own biochemistry and genes by magical thinking or psychotherapy. I see much of the depression in the postmanic traumatic neuroses as the same depression H.G. Wells felt in *Mind at the End of Its Tether*, when he realized he could not change the facts of the world (3).

I am at present preparing a manuscript further discussing my experiences in psychotherapy with bipolar patients.

ROBERT BENSON, M.D.
Seattle, Wash.

Dr. Kotin Replies

SIR: Dr. Benson's chief complaint seems to be my use of the word "responsibility," which I quoted, in admiration, from Semrad and Zaslow (1). Dr. Benson is reacting as if I wanted to blame the patient. I meant quite the opposite. Guilt, self-blame, and "a veiled wish for omnipotence" can be regarded as irresponsible emotions. Through reversals of active and passive modes, the depressed person believes himself guilty of creating situations that actually are beyond his conscious control (e.g., psychotic decompensations and losses). Conversely, he does not feel able to do even that which he can (e.g., get out of bed). Meyersburg and associates (2) have discussed this mechanism and its therapeutic implications in detail. By the patient taking responsibility for his illness I mean that he should be helped not to deny his experience, to claim its authorship as with a dream, to experience his psychotic and nonpsychotic selves as continuous, and to integrate the experience. This is not easy, and many patients and therapists will not make the attempt.

Dr. Benson stresses the similarities between his patients' and his own feelings during the patients' manic episodes and how they later can recall together "the horror of the memories retained . . ." (3). Perhaps we are not so far apart after all. In some cases, I have stressed to patients the "partly biological and hereditary nature" of their illness in an attempt to relieve *their* guilt when time or resources were limited or when it seemed to me that further integration was not a possibility for the particular patient. I am not sure these interventions have been helpful, however. I believe that if the patient and therapist are able, it is far preferable to attempt to fully integrate experiences, psychotic or otherwise, rather than to integrate them partially or not at all.

Although some individuals may be genetically predisposed to develop manic-depressive illness, the psychological life of the individual may be of crucial importance in determining whether he becomes ill. It is my clinical impression that psychological events (specifically intrapsychic object losses) do antecede all clinical affective illness, as was suggested in the important works of Rahe and associates (4) on life stress and illness of all types. More subtle, and not easily quantifiable, work with children (5–7) has explained how a complex and unique, psychotic or normal, individual results from the interaction of genetic givens and environmental exigencies. Similar but much more complex processes no doubt occur in adults. In support of using psychotherapy with postmanic patients on lithium, Dr. Benson quoted Abraham (8) as saying that psychotherapy alone can alter the course of manic-depressive illness, but this is what he argues so strongly against in his letter.

The question of whether mania may be precipitated by intrapsychic or interpersonal events has yet to be thoroughly studied. Most biologic psychiatrists have assumed that mania is not precipitated by psychological events. Superficial research has been claimed as evidence for this, but most studies have been primarily descriptive, and only a few brief questions have been asked about precipitating events. When cases of "endogenous" depression were exhaustively studied, it was found that virtually *all* severe depressions were preceded by significant environmental alterations (9). A similar detailed study of environmental precursors of mania has not been reported to my knowledge.

Examining the Pavement

SIR: "Crime and Violence Among Mental Patients" by Arthur Zitrin, M.D., and associates (February 1976 issue) is an elegant illustration of the wisdom embodied in the folk observation that the road to hell is paved with good intentions.

While it warrants repeating as often as possible that discharging patients from psychiatric hospitals without adequate community support and treatment programs is a travesty, basing such statements on the kind of data presented in this article is needlessly self-defeating. I should think that anyone with Dr. Zitrin's experience would recognize the glee with which opponents of any diversity and heterogeneity in a community would light on his reported results to buttress their arguments in public forums. This is not to suggest that data should be suppressed simply because they might be used in an undesirable manner. Rather, it is to emphasize that in studies which have as inflammatory a potential as this one, extreme care must be exercised to introduce all possible considerations into the research design and data analysis. The authors appeared to be trying to do this in justifying their use of arrest records, a now generally discredited indicator of criminal activity (even the U.S. Civil Service Commission no longer asks for this information on employment applications), by pointing out that conviction records, a more certain reflection of criminal activity, would be unreliable because of the large number of indicted psychiatric patients who are diverted from the criminal justice system prior to trial. However, the authors do not consider the fact that so many of these patients, by virtue of their obvious strangeness or of being known to the police in connection with their original hospitalization (which very likely involved testimony as to their dangerousness), are likely to be selectively marked for arrest and questioning—especially in connection with violent crimes. This oversight is particularly unfortunate when one realizes that one of the factors initially contributing to the discrediting of arrest records was a recognition of the existence of just such discriminatory arrest practices, albeit applied on racial and class bases.

This consideration opens to question the validity of a key measure used in the study and thus raises doubt about the significance of the reported findings. Had this factor been properly taken into account in the research design, the authors would have recognized that the study, as described, is inconclusive. Not until it had been demonstrated that innocent psychiatric patients are not arrested with greater frequency and on less cause then the rest of the population could any valid conclusions about the violence of "mental patients" be drawn. True, publication of the study would probably be considerably delayed by requiring such a preliminary finding, since it is likely to be particularly difficult to demonstrate because so many of this group are diverted from the criminal justice system prior to trial, which is our only reliable indicator of innocence or guilt. Nevertheless, the research literature and the public would have been none the worse for nonpublication of this article. There are already sufficiently compelling arguments for good community care. One should not have to rely on a study of questionable validity that can also be used to oppose all community programs, and we do not need to provide otherwise well-meaning police officers with a "scientific" basis for arrest practices that ultimately amount to no more than harassment of psychiatric patients.

SIMON L. AUSTER, M.D.
Fairfax, Va.

Dr. Zitrin and Associates Reply

SIR: We admit to the good intentions Dr. Auster ascribes to us, but shouldn't the conclusion about our destination await a careful follow-up?

Dr. Auster argues by asseveration: saying things positively makes them so. What authority is there for his flat assertion that arrest records are "generally discredited" indicators of criminal activity, particularly for psychiatric patients? What is the evidence that patients "are likely to be selectively marked for arrest and questioning—especially in connection with violent crimes"? Reports from state hospital directors, lawyers for New York's Mental Health Information Service, police officers, and our own observations at Bellevue Hospital support the opposite conclusion. There are communities near state hospitals in New York where relatively large numbers of discharged mental patients reside. When those patients commit public nuisances or other misdemeanors that would normally result in arrest, they are often simply returned to the local state hospital. In other areas, minor violations are usually overlooked by the police when the offender is recognized as a mental patient. In Manhattan many patients are brought to the psychiatric division of Bellevue for behavior that would certainly lead to arrest if committed by others. It is possible that former mental patients who commit serious crimes are not as capable of evading arrest as are other criminals, but data on this point are also lacking and difficult to obtain.

We have cited accounts of the abuse and exploitation of mental patients by callous, cruel, and unscrupulous individuals in the community. But where is the evidence that there is substantial harassment of such patients by the police, with or without the support provided them for such action by research findings such as ours?

Dr. Auster's insistence that no valid conclusions about the violence of "mental patients" could be drawn until "it had been demonstrated that innocent psychiatric patients are not arrested with greater frequency and on less cause than the rest of the population" implies that our conclusions are invalid. The only conclusions we drew were that our data on arrest records "are not in agreement with earlier reports based on state hospital patients" but are "in general agreement" with

more recent studies on the same subject.

The answer to the question that Dr. Auster poses can only be supplied by follow-up studies on those arrested. However, he agrees with us that the diversion of many patients from the criminal justice system would leave the issue of their guilt indeterminate, if we accept the criterion of conviction as evidence of guilt. Although we are engaged in such a follow-up study as part of an examination of the diversionary process, we do not agree that publication of our findings should await the conclusion of that investigation.

In this connection, Dr. Auster's second point seems to us more important. Despite his disclaimer, he is clearly implying that the results of scientific inquiry should be withheld if they are potentially "inflammatory" or can be misused for socially undesirable ends. While we feel that the greatest care must be taken to safeguard against the misuse of the fruits of scientific investigation, whether in the fields of genetics, nuclear physics, or mental health, we disagree with a posture that smacks of antiscience vigilantism. History tells us clearly of the consequences of such curtailment of free inquiry, first done for noble goals to be sure, but soon used for debased ends.

Arnoff (1) has pointed out that policy toward mental illness has often been determined by short-range political expediency and the pressures of social reform rather than on the bases of hard fact and clinical experience. He writes, "There comes a time when reformist zeal must be matched against available data, and while the humanistic goals may persist the paths to them must be modified. This clearly is long overdue for mental health." We agree.

Confidentiality in Military Psychiatry

SIR: I am writing this letter to protest two aspects of the U.S. Army alcohol and drug treatment program—the lack of confidentiality and the failure to separate counseling from probationary functions.

While in the Army (my tour was from July 1969 to December 1975), I once was asked by military intelligence to furnish evidence related to alleged alcohol abuse by a patient I had been seeing in psychotherapy for several months. I referred them to another psychiatrist to conduct the evaluation, but they insisted on obtaining the information from me. They demanded to see the patient's psychiatric records but fortunately I had kept none. I obtained legal advice to the effect that I could be imprisoned if I did not answer their questions. Finally, I was forced to give them a long statement, essentially stating in detail that I did not have enough information to answer any of their questions.

The problem of confidentiality has become worse recently. Since late 1975, every soldier and dependent treated at a drug and alcohol abuse treatment center (or at any mental hygiene or medical facility in the Army) has been asked to sign a statement to the effect that any information he/she gives can be used by the Army to "conduct authorized investigations" or for "other lawful purposes including law enforcement and litigation."

Another limitation to the Army drug and alcohol program is the lack of separation between counseling and probationary functions. After a patient is admitted to the program, he must demonstrate 60 days of good behavior in his unit and 8 weeks of "clean urines," or he may be discharged from the Army because of "rehabilitation failure." In other words, he is placed on what amounts to probation. This probationary function of the program should be separated from its counseling function. A counselor should not have to coerce his patients to attend sessions or discipline patients when they misbehave; a probation worker should not have to see unwilling, unmotivated patients for 40–50 minutes each week. This current combination of functions has had a demoralizing effect on counselors and has been antitherapeutic for patients.

Psychosurgery for Political Purposes

SIR: Over the past few years, letters to the editor of the *Journal* have dealt with controversies related to psychosurgery, including its possible use for political control. However, to the best of my knowledge, no detailed documentation on this subject has been available in a scholarly journal. Those who have been following the controversy may therefore be interested to know that the *Duquesne Law Review* has recently published my article "Psychosurgery for Political Purposes" in a special symposium on medical experimentation and behavior control (1). The article documents how a small group of influential psychiatrists, neurologists, and neurosurgeons began promoting psychosurgery for political purposes following the urban riots of 1967 and 1968, including its use to treat rioters, protesters, and leaders of urban disorder. The article describes how this group systematically rode the wave of public fear to obtain state and federal funding for their projects. A limited number of reprints are available at the address below.

Confirming a Side Effect

SIR: In "Thioridazine and Sexual Dysfunction" (January 1976 issue), Joel Kotin, M.D., and associates reported a high (60%) incidence of sexual dysfunction in men taking thioridazine. The experience at our aftercare program at Northwestern University is in complete agreement with their findings. In addition to those persons who have complained rou-

tinely of the sexual dysfunction, two patients presented with extreme panic, perplexed by their ejaculatory incompetence but feeling ashamed to discuss the actual symptom. Direct questioning, reassurance, and medication change solved the problem quickly.

In practice, we no longer prescribe thioridazine to male patients. Curiously, we have had three patients who insisted on thioridazine. One man found that it was an excellent treatment for his premature ejaculation. A second was an extremely regressed schizophrenic who felt the drug enabled him to masturbate more frequently. The third was a guilt-ridden obsessive individual who felt much better about masturbating if he did not ejaculate.

An Error Corrected

SIR: I think there is an error on page 210 of "Recent Developments in the Drug Treatment of Schizophrenia" by John M. Davis, M.D. (February 1976 issue). I doubt that the author meant to say "60 mg/day of trifluoperazine is equivalent to about 1 g/day of chlorpromazine. . . ." Later in the same sentence, a different standard of equivalency is implied.

CARL N. BROWNSBERGER, M.D.
Newton Lower Falls, Mass.

Dr. Davis Replies

SIR: Dr. Brownsberger is quite correct. A typing error was made in the original manuscript; the sentence should read "60 mg/day of trifluoperazine is equivalent to about 2 g/day of chlorpromazine." The calculation is as follows: since 2.8 mg of trifluoperazine is equivalent to 100 mg of chlorpromazine, 60 mg/day of trifluoperazine would be equivalent to 2.1 g of chlorpromazine. Since 734 mg/day of chlorpromazine is the normal daily dose, 60 mg of trifluoperazine would be 3 times the equivalent normal daily dose of chlorpromazine. Hence 600 mg would be about 30 times the normal antipsychotic dose.

A similar calculation two paragraphs below this statement indicated that 15 mg of trifluoperazine is equivalent to 535 mg/day of chlorpromazine. Since this article went to press, another study (1) has appeared that also found that megadose treatment using 1200 mg/day of fluphenazine (or 100 g chlorpromazine equivalent) is no better than 30 mg of fluphenazine (or 2.5 g chlorpromazine equivalent). The purpose of these calculations is to convert the dosages of the different drugs used in the various studies to chlorpromazine equivalents. This provides a standard of comparison for the dosages used in these studies.

Prospective Studies on Released Inpatients

SIR: Our own review of the literature, like that in "A Note on Some Recent Studies on Released Mental Hospital Patients in the Community" by Leona L. Bachrach, Ph.D. (January 1976 issue) has shown that there are few comprehensive prospective studies in this area. This lack has spurred us to complete our own prospective research project on the continuity of care of psychiatric inpatients as they are released into the community (preliminary papers have already been published [1, 2]). The study focuses on a cohort of 200 patients with all diagnoses, not just selected groupings as Dr. Bachrach suggested. We are attempting to focus on a variety of criteria that deal with postrelease functioning, rather than limiting the study to recidivism, as she also suggested. We are looking at patients' social functioning, living arrangements, outcome of aftercare plans, and level of economic capacity.

There are not more studies at this time because such research is extremely difficult. First, there is the problem of the many variables one must consider. Another difficulty is creating a milieu in which this type of data can be adequately collected, the major problem being staff resistance. Funding is extremely skimpy. We are hopeful that the rest of the papers that will come out of our research project will be of interest to the readers of Dr. Bachrach's article, since they, like us, are interested in improving the quality of patient care and the delivery of health care in a very complex system.

BOOK REVIEWS

Selected Papers of Ernst Kris, *by Ernst Kris. New Haven, Conn., Yale University Press, 1975, 512 pp., $20.00.*

The felicitous grouping of Ernst Kris's papers into four categories highlights the breadth of his contribution to psychoanalysis. Although the subjects seem disparate, Kris's creative insights weave through all the papers and integrate his work.

In the first group of papers, which deal with the psychology of childhood, Kris emphasizes the importance of validating by direct observation the genetic propositions of psychoanalysis that had been derived from reconstructions. In several papers he presents the observations derived from his participation in the longitudinal studies at the Yale Child Study Center, which demonstrated the effects of conflict, ego maturation, and autonomous ego function on both normal and pathological personality development.

Although Kris's case studies illustrate that narcissistic supplies are an essential spur to emotional and intellectual growth and to the unfolding of special gifts and talents, they also indicate that optimum degrees of frustration and gratification have to be more carefully delineated. The effect of a traumatic situation depends not only on the nature of the trauma but also on the stage of the child's development at which it occurs. Parental attitudes are decisive, but these are not fixed; they vary in response to the child's development and are determined by intrapsychic issues that are often unconscious and not easy to identify. Because unconscious factors also play a role in the child's responses, which are elaborated into fantasies, direct observation has to be supplemented by psychoanalytic observations in order for one to arrive at valid conclusions.

Interest in the unconscious and the processes by which memories and other unconscious material become conscious dominates the second group of papers, in which Kris's unusual gifts as a clinician and synthesizer of psychoanalytic thought are amply demonstrated. For the unconscious to become conscious, the ego must be receptive to the id. In the clinical setting, this receptivity occurs when interpretations remove barriers to recall. This process, which is largely preconscious, depends on the ego's capacity to integrate conflicts and trauma that have been barred from consciousness. In the "good analytic hour," i.e., one in which spurts of understanding occur, there is evidence of this process. Controlled regression occurs and the ego, which has the ability to observe and to contain affect, integrates and synthesizes events of the past as they affect the present.

The aim of analysis is not merely to recover childhood memories but to understand and modify the effect that unfulfilled wishes and longings have on current situations. That patients are struggling not merely with actual past events but with fantasies and psychic realities is illustrated especially in the paper on the personal myth, in which Kris discusses the substitution of fantasy for painful reality.

The subject of the third group of papers is the history of psychoanalysis. In these papers Kris emphasizes the importance of the development of the concept of the ego. He traces the modification of this concept as it was influenced by clinical observations and their impact on all aspects of psychoanalytic theory. The ego cannot be understood in isolation from other psychoanalytic propositions because its development is influenced by drives, by the superego, by object relations, and by autonomous ego attributes.

In the last series of papers, Kris applies psychoanalytic insights to the subjects of prejudice, propaganda, morale, and creativity. He skillfully demonstrates that although each of these phenomena has its roots in basic human needs, they are all multidetermined. Kris's capacity to explicate the effect of the interaction of many levels of psychic organization on human behavior is noteworthy and is especially evident in his paper on creativity.

Reading Kris's papers as they are presented in this volume is a rewarding experience because it enables the reader to follow his creative insights and challenging observations through the many contexts in which he presents them. Although Kris's work has long been held in high regard, the impressiveness of his contribution becomes more apparent when these papers are read in sequence.

Research in the Service of Mental Health: Report of the Research Task Force of the National Institute of Mental Health. U.S. Department of Health, Education, and Welfare Publication 75-236, *edited by Julius Segal, Ph.D., Donald S. Boomer, Ph.D., and Lorraine Bouthilet, Ph.D. Rockville, Md., NIMH, 1975, 444pp., no price listed (paper).*

This is an extensive and detailed report by a large task force of the National Institute of Mental Health, backed up by committees involving 300 scientists who reviewed the work of NIMH since its inception in 1948.

NIMH has been the nation's major source of support for research in the broad domain of mental health. It has also carried out many investigations in its own laboratories and facilities. All told, thousands of investigators have pursued problems under NIMH auspices "that span the range of mental health concerns and that involve the full spectrum of behavioral disciplines." The number of identifiable research efforts has increased impressively—from 38 in 1948 to 1,497 in 1972. During this period more than a billion dollars of federal money has been invested in the pursuit of new knowledge and techniques in the fields of mental health and behavioral science.

Many experts called to the task asked the following questions: What progress has been made? What research areas are expected to be most profitable in the future? Which administrative and organizational support mechanisms are best to reach stated goals?

The scope of the review is very broad. The work was carried out by 10 study groups in such diverse areas as biological and physiological processes, psychological processes, social and cultural processes, mental illness, behavior disorders, drug abuse, alcoholism, social problems, treatment

techniques, mental health services, and research information and utilization.

The chapter on the organization's history takes us from the work of the National Committee for Mental Hygiene under Clifford Beers in 1909 through the various activities preliminary to the founding of the National Institutes of Health (mainly through the efforts of Walter Treadway and Lawrence Kolb, Sr.) to the establishment of NIMH under Robert Felix, whose outline for the program became the working paper used by the Congress that passed the National Mental Health Act in 1946. Under Felix' leadership the research grant program, grant review process, intramural program, and other major expansions took place. Programs for training, small grants, international research, applied research, demonstrations, and information systems also flourished under his leadership.

When Bertram Brown became the director of NIMH, child mental health was designated as its top priority and more prominence was given to drug abuse and alcoholism. The report does not discuss in detail the reorganization that became effective in July of 1973, which patterned a new relationship among alcoholism, drug abuse, and mental health and is known as the Alcohol, Drug Abuse, and Mental Health Administration (ADAMHA).

Chapter 3 of the report presents an overview of support of research activities, showing their great diversity. Funds committed to each field are detailed in several important tables that present an impressive picture of the evolution and differentiation of thought and activity in the burgeoning disciplines.

Chapters 4, 5, and 6 deal with basic research in biology, psychology, and sociology, respectively. These are followed by an extensive discussion of research on behavior disorders and such categorical programs as alcoholism, childhood psychosis, schizophrenia, and drug abuse.

The chapter on research in social problems emphasizes the importance of further advances in design and in improved methods of handling data. The chapter on research in mental disorders covers a whole range of modalities thought to be clinically useful, such as psychoanalysis, family therapy, milieu and community care, encounter groups, token economies, aversive therapies, biofeedback, and modeling. The psychopharmacological treatment of mental disorders as well as other somatic therapies come in for intensive discussion.

The section on research in mental health services reports progress made on case-register technology, admission rates, demography, automated data systems, epidemiology, school programs, rehabilitation, foster care, day care, home care, and the essential components of effective delivery systems.

The final chapters deal with the dissemination and use of research information and the administration and organization of research programs.

Each chapter is carefully written and is followed by an extensive and useful bibliography. The 300 workers who were involved in developing this summation did their work extremely well. The volume is a gold mine of information on what has happened in the United States in the last quarter-century and clearly shows the dominance of NIMH in cultivating, energizing, and directing the research activities of the nation.

It would take a long book review, indeed, to do justice to the broad and detailed analytic and synthetic work reported in this volume. NIMH is to be congratulated on another contribution to the history of research endeavors in this country. One hopes that the future holds equal promise of federal support for the nation's scientists. The book is to be commended to every researcher now in the field and to all prospective researchers. Administrators of all kinds of scholarly and academic facilities will want to be conversant with its contents, and Congressmen and executive officers of government will find much to appreciate in this landmark contribution to American history.

Mental Disorder in Earlier Britain: Exploratory Studies, *by Basil Clarke. Cardiff, Wales, University of Wales Press, 1975, 327 pp., £10.00.*

For too long a time it has been traditional to speak of the middle ages as the dark ages, thereby implying that it was a time of stultifying inactivity. We have gradually discovered that using this term is a commentary on our contemporary knowledge more than anything else. Recent scholarship has opened up this previously obscure period of history and has revealed it to be full of riches. In its own fashion, this book by Basil Clarke is a contribution in that direction.

Clarke's studies of mental illness in early Britain cover a range from the early Celtic societies through the end of the seventeenth century. Clarke recognizes that he is undertaking a very ambitious project and therefore subtitles his book *Exploratory Studies*. He is not trying to digest and give us the full benefit of his extensive knowledge, which is really a challenge for a subsequent work. Rather, he presents us with an extensive survey that makes use of not only the medical literature but a wide range of evidence from other sources.

The first half of the book takes one through the fourteenth century. Starting with the Celtic literature, Clarke explores the beliefs of the medical Druids, folklore, religious literature, various early laws, the tradition of the wild man, and a wide variety of other topics.

That nonmedical literature can make valuable contributions to the understanding of the psychiatry of that early period can be seen not only in Clarke's book but also in some other recent writings that he does not cite. I think particularly of the excellent survey of Penelope Doob of the concepts of madness seen in middle-English literature (1). Judith Neaman has written a study of medieval literature in which she presents a picture of madness by synthesizing what can be learned from the literature, art, history, and science of the day (2). The role of the devil in matters of madness appears in both of these works and more extensively in a less recent book by Jeffrey Burton Russell (3). With these three books plus Clarke's in hand, any serious student can extend his or her knowledge of the medieval concepts of madness.

The middle section of this book provides source materials that are extremely valuable. The first reports on a group of patients who had been treated at St. Bartholomew Hospital in London in the twelfth century and the second on a series of patients who appeared at the tomb of Henry VI at Windsor in the late fifteenth century to seek alleviation of their problems. The final account is devoted to the sudden illness of King Henry VI of England at the age of 31 in 1453. His illness resembled a catatonic stupor from which he gradually recovered only to suffer from intermittent periods of difficulty thereafter. Clarke explores the hereditary possibilities in Henry VI's family and finds one clear-cut predecessor in his maternal grandfather, King Charles VI of France.

In concluding his book, Clarke reviews the sixteenth and seventeenth centuries; in regard to the former he pays considerable attention to popular medicine and magic, and in regard to the latter he includes a review of the extensive case studies by Dr. John Hall, the son-in-law of William Shakespeare.

This is indeed a very comprehensive book. The reader will find an enormous amount of information about psychopathology, the social reaction to psychopathology, theory, diagnosis, treatment, hospitals, and forensic factors. Its major defect, however, is a difficulty in finding the material. This arises from three factors: 1) the coverage is encyclopedic, 2) the subject index is highly inadequate, and 3) the book is so full of details and written in such turgid prose that the reader encounters a problem in rapidly locating the subject that interests him. However, the subjects are there and the reader will be rewarded for his efforts in searching for the information. No one interested in the history of psychiatry or the history of this period in Britain will be able to do without this important volume.

ERIC T. CARLSON, M.D.
New York, N.Y.

The Effect of the Method of Payment on Mental Health Care Practice. Report 95, *by the Group for the Advancement of Psychiatry Committee on Governmental Agencies. New York, N.Y., GAP, 1975, 130 pp., $4.00 (paper).*

This little volume, with its unassuming title, is a most valuable contribution to an emerging body of literature concerned with future patterns of mental health care in general and the influence of impending national health insurance in particular. The report compares six mental health care systems (private practice, a health maintenance organization, a community mental health center, a state mental health system, the Veterans Administration system, and the military system) in terms of major common variables. The contrasts are sharp.

It is disconcerting, to say the least, to acknowledge the range of unresolved issues that still characterize the delivery of mental health services in the United States. They provide a rough measure of the organizational and scientific issues that remain controversial in our field. As long as we cannot agree how to diagnose psychiatric patients or whether a medical model or some social model should be used to understand mental illness, it follows that there must be corresponding differences in criteria for selecting patients for treatment, in models of therapy, in quality control, in professional credentials, and in a range of related issues.

The failure thus far of scientific methods to answer many of the crucial questions in psychiatry is common knowledge. What has been less clear is the role of economic factors in forcing practical answers to so many of these questions. Despite all of our knowledge and sophistication, it may still shock many to learn that a patient suffering almost any form of mental illness is most unlikely to receive the same treatment for his condition in different mental health care settings. The sample health maintenance organization reported in the book would most likely prescribe short-term psychotherapy, with return to function as the primary treatment objective. The same patient would probably be assigned to group therapy in the community mental health center or to long-term individual psychotherapy by a psychiatrist in private practice. Here is evidence not just of a dual health care system—one for the rich and one for the poor—but of a multitiered delivery system whose configuration differs in almost every imaginable dimension as a function of variables that are essentially economic.

The book wisely and successfully avoids polemics and proselytizing. Each of the six systems is presented fairly and openly, without hiding inherent weaknesses or flaunting inherent strengths. All five of the organized mental health care settings—different as they are—are more like one another than any one of them is like private practice. Although private practice continues to offer the widest range of treatment services and the most flexible and refined options for the development and application of an individualized treatment plan, it is also the system most rigidly locked into a medical model of illness that excludes many social considerations. Private practice also remains the most exclusive form of treatment because so many cannot afford it and have no insurance to cover the costs.

The ideal for the future would embody the best of what now exists, and this report ends with a call for funding mechanisms that would guarantee equity of care for all, professional autonomy, and personalization of treatment and that would also allow, if not encourage, an open diversity of mental health care mechanisms.

The final chapters of the book, which compare the six systems and provide succinct concluding recommendations, will prove sufficient to the topic for many readers. However, the detailed chapters on the different forms of service organizations are surprisingly interesting. Although probably not destined to become a best-seller, *The Effect of the Method of Payment on Mental Health Care Practice* is surely required reading for anyone involved in health care planning. The book will raise the level of sophistication regarding problems of mental health care for any reader who takes the time to seek different points of view on this issue of timely interest to our profession.

JUSTIN SIMON, M.D.
Berkeley, Calif.

Cases of the Reincarnation Type, Vol. I: Ten Cases in India, *by Ian Stevenson, M.D. Charlottesville, Va., University Press of Virginia, 1975, 367 pp., $20.00.*

During my visit some years ago to a country behind the iron curtain, a colleague attempting to impress me with how far the post-Stalin thaw had progressed asserted that anyone in his position could now maintain any viewpoint he pleased on any question at all. "Even on Trotsky?" I asked. "Certainly not," he snapped, as if my question could not have been more preposterous. Equally preposterous among otherwise open-minded Western scientists, I suspect, would be the question of reincarnation, and this might even be said to be the case among most people in the field of parapsychology.

To begin with, the idea of reincarnation (defined in Hinduism as the union of a soul with a new physical body after the death of the physical body with which it was previously associated) appears to be irreconcilable with established fact in biology and evolution, to say nothing of the rest of science. Next, the hypothesis obviously does not lend itself to any kind of experimental test. Finally, the idea of karma (the effects of behavior in one life on one's fortunes in another life), with which it is frequently associated, is as completely useless a blank check as has ever achieved the status of a seriously entertainable notion.

Despite all this, the factual basis for the widespread belief in reincarnation turns out to be as legitimate a subject for investigation as anything else in the natural world. Circumspectly sidestepping the issue of karma, Dr. Stevenson, Professor of Psychiatry at the University of Virginia and author of an earlier volume on reincarnation (1), deals in this first of several intended volumes solely with his checking and rechecking of anecdotal and documentary data relating to 10 selected cases of the reincarnation type in India. The work took 16 years of dogged research. In all 10 cases studied, several of the persons involved (most of whom were believers in Hinduism, in which the doctrine of reincarnation is central), believed that reincarnation had occurred. Dr. Stevenson presents his material in a lucid, detailed, judicious, and always interesting manner.

Reincarnation type cases might run somewhat along the following lines:

A child, shortly after he starts to speak, begins talking of things, places, and people that appear to be utterly strange to the parents. The child may even behave in a way that cannot easily if at all be accounted for in terms of the circumstances of his upbringing. The child may relate all this to a previous life he claims to remember having led.

If the child persists in such talk and behavior, which, although often quite trying to the family, appears to be easily differentiable from known types of mental disturbance, the parents or friends of the family sooner or later start to make inquiries concerning persons presumed to be deceased to whom the child's statements might apply. They might even use the personal columns in newspapers for these inquiries. Sometimes, however, the child's statements about his name in the "former life" or the town he lived in are so highly specific that it does not take much searching to find the family that appears to be the source of the statements. Once contact is established, additional information verifying or contradicting the child's statements is usually found, and the child may be taken to the family he claims to have been his original family.

Here begins the process of "recognition," whereby the child takes his parents and others through complicated streets and alleys and, with almost somnambulistic precision, directly to the place at which he claims to have resided or worked in the former life. He then greets various persons he may meet there by name and with appropriate behavior, which is sometimes quite negative. Gradually the chinks in the picture are filled in—likes and dislikes, special idiomatic phrases, nicknames, and names for objects. Occasionally information having to do with criminal or morally scandalous activities that are highly embarrassing to the second family are uncovered.

Obviously this kind of procedure is beset with pitfalls. Reliable primary data have to be winnowed out from rumor, deliberate or inadvertent falsification, the possibility of hoax, and the snowballing potential of overeager witnesses. All possible means whereby information about the second family could have been conveyed to anyone remotely connected with the child's family and thus to the child have to be investigated and evaluated. It is in the care with which this has been done in these 10 cases that Dr. Stevenson makes his major contribution.

According to Dr. Stevenson, after chance and normal means of communication between the two families involved have been rendered more or less implausible as explanations, one is left with two alternatives: reincarnation or a two- or three-year-old child's acquiring information paranormally and then weaving it into a scenario that has all the earmarks of reincarnation. Stevenson leans toward the former hypothesis, but it almost goes without saying that neither hypothesis will be acceptable to most minds bred in a materialistically oriented scientific tradition. Many persons within the field of parapsychology, on the other hand, may not agree with the simple set of alternatives that Stevenson adduces and might well consider the problem far more complex.

Regardless of his bias, the psychiatrist will hardly fail to note that most of the cases presented in this volume occurred in a context of intrigue and violence, at least within the families of the persons allegedly reincarnated. In 7 cases there was murder or suspicion of murder; 6 of these involved the persons murdered. In addition, 1 child had been separated in infancy from his real parents, and in 6 cases there was marked upward movement in economic status, caste, or both. Indications of such upward movement were often the first signs of anything unusual—a child refused to eat or behave as he was supposed to in a lower station and persistently professed to have been of a higher one. In no case was there a lowering of caste or economic status.

Surely factors of this sort in no way invalidate the primary data themselves, but they do invite speculation along dynamic lines. Is "reincarnation," whatever its existential status, symptomatic? Is there, in suitable soils, a "reincarnation syndrome"? If so, how does this manage to translate itself into a kind of reality, a question clearly not too unlike one that pervades psychiatry (and parapsychology). Whatever way such issues are resolved (if they ever are), Dr. Stevenson has done a signal and signally courageous service in bringing them so insistently to the fore.

JULE EISENBUD, M.D.
Denver, Colo.

Depression and Human Existence, *edited by E. James Anthony, M.D., and Therese Benedek, M.D. Boston, Mass., Little, Brown and Co., 1975, 546 pp., no price listed.*

During the last few years there has been a striking increase in the level of professional interest in the problem of depression. It has been suggested that the incidence of clinical depression is on the rise, although there are no sound epidemiological studies to verify this impression. One can infer, however, that a society in which the experience of loss has become commonplace—as divorce increases and a sense of community is weakened—will be fertile ground for depression. It is also possible that biological changes resulting from the very food we eat and air we breathe may have an effect

on the mind, even as it has been recently demonstrated that certain children manifest psychotic behavior as a result of ingesting artificial food flavoring. Helplessness, loneliness; and discontinuity are common elements in depression and rather characteristic features of the current culture.

Drs. Anthony and Benedek have attempted to put together a comprehensive review of the subject of depression, with particular emphasis on the experience of being depressed as part of a universal human vulnerability. The contributors to this volume are notable and outstanding. George Winokur, for instance, discusses the issue of heredity in affective disorders, Arnold J. Mandell reviews neurochemical aspects, and Edith Jacobson discusses the relationship between self-esteem and depression from a psychoanalytic point of view.

Unfortunately, as a textbook the editors' efforts do not quite succeed. To begin with, the ordering of material does not follow a sufficiently logical course. Immediately after an introduction that attempts to review the question of depression from a psychoanalytic as well as an existential viewpoint, there are 3 chapters on biological aspects, then 2 on cultural and social influences. Most of the remaining 16 chapters are heavily and traditionally psychoanalytical in emphasis. More to the point, there are certain specific gaps in information. For instance, the chapter on biochemical and neuropharmacological research in the affective disorders explores at length (and somewhat uncritically) the biogenic amine hypothesis, but it fails to give adequate coverage to endocrine and mineral changes that may be of equal importance in such disorders. The chapter by Edith Jacobson on the psychoanalytic treatment of the depressed patient contains many useful clues and directions for therapy, but it focuses exclusively on a one-to-one treatment setting; nowhere in the book are group approaches (primarily of value for depressed patients who also have characterological difficulties) or family therapy (of central importance for the depressed person whose relationships within the family are in disequilibrium) discussed. Nor is there a useful discussion of the integration of biological treatment with psychological therapy and environmental modification.

To be sure, creating a multiauthored text is a major labor. When the editor has a particular concept in mind, it is especially difficult to select and shape the material that various contributors may submit to establish this hypothesis. In their introduction, Drs. Anthony and Benedek approach the concept that depression itself may be an existential human experience and intimately related to the survival of the human organism under certain kinds of stress. In the final chapter, Michael Basch attempts to develop the thesis that depression is a "general system dysfunction rather than a unitary disease entity." However, this effort at synthesis is never really successful. On the whole it is obscured throughout the book by repetitiousness (Freud's *Mourning and Melancholia*, for instance, is discussed again and again) and by a common problem that plagues psychiatry and the behavioral sciences in general: the unclear use of language. Because language is essentially a way to communicate concepts, one must question how precisely these concepts have been thought through.

The strongest and most interesting chapters in the book are those written by the editors themselves. For instance, Dr. Anthony's chapter on the influence of a manic-depressive environment on the developing child is intriguing, provocative, and original. In two other chapters, the focus he directs toward the nature of depression in childhood and adolescence, where it is often overlooked, is well presented. Rather than assembling the material as they have done, it might have been far more valuable for the editors to have concentrated on writing their own book because their knowledge of the subject is well developed, their personal experience with it is unique, and their own theoretical vision of what depression may be all about is a potentially valuable beacon to researcher and clinician alike.

Child Personality and Psychopathology: Current Topics, Vol. 2, *edited by Anthony Davids, Ph.D. New York, N.Y., Wiley-Interscience (John Wiley & Sons), 1975, 252 pp., $16.95.*

In reviewing the first volume in this series (April 1975 issue of the *Journal*), I felt that it met the needs of the child psychiatrist and child therapist in the field and in the university setting. This second volume establishes this series as a must for all who are interested in child development and psychopathology. Each paper is timely and original and presents research in a stimulating fashion. Anthony Davids is to be congratulated for his selection of papers, as well as for the fact that one has a feeling that the papers flow together.

The volume is divided into three sections. The first focuses on cognitive and personality development. Two outstanding papers are included here. Even though Mary Engel, Herbert Nechin, and Arthur Arkin caution the reader against assuming causality from the results they report in "Aspects of Mothering, Correlates of the Cognitive Development of Black Male Infants in the Second Year of Life," it is difficult not to do so when one is presented with such excellent material. Robert Liebert and Rita Poulos' paper, "Television and Personality Development: The Socializing Effects of an Entertainment Medium," is the best paper I have read on this difficult subject. Their statement that "television captures the attention of nursery and elementary school age children for an average of three hours per day, seven days a week, so that by age 16, most children in the United States will have spent more time watching television than going to school" makes this paper a must. The authors present a very systematic study of this socialization process in detail.

The second part of the book deals with psychophysiological and behavioral disorders. Here again are two timely and excellent papers. Kenneth Purcell's paper, "Childhood Asthma: The Role of Family Relationships, Personality, and Emotions," broadens our understanding of the developmental dynamics of families. This paper deals with asthma subgroups, allergic potential classification, and experimental separation of asthmatic children from their families. C. Keith Conners' paper, "Minimal Brain Dysfunction and Psychopathology in Children," comes at a time when all practitioners are being flooded with data and presents an excellent review of papers dealing with this subject. A great deal of work has gone into the biological and psychosocial aspects of minimal brain dysfunction and the effects of altering the central nervous systems of hyperkinetic children.

The third part of the book deals with childhood psychosis. Two papers deserve special mention. Norman Garmezy's excellent work in schizophrenia is well known; his paper, "The Experimental Study of Children Vulnerable to Psychopathology," opens a new and intriguing perspective on children at risk. He presents an in-depth look at the world literature dealing with children at risk for schizophrenia. His conclusion from this survey is that we are at risk if we jump to conclusions that seem so logical that they smack of commonsense. Sarnoff Mednik, Harme Schulsinger, and Fini Schul-

singer's paper, "Schizophrenia in Children of Schizophrenic Mothers," represents the beginning of really being able to define the concept of "at risk" and the beginning of a plan to deal with these problems.

The Creation of Deviance: Interpersonal and Organizational Determinants, *by Richard Hawkins and Gary Tiedeman. Columbus, Ohio, Charles E. Merrill Publishing Co. (Bell & Howell Co.), 1975, 363 pp., $11.95.*

This book provides a sociological perspective on various social and psychological processes thought to be involved in the creation and societal control of deviance. It offers both a review and an assessment of a large body of sociological (and, to a lesser extent, social psychological) writing that attempts to understand how and why some people become labeled deviant and what happens to them once they are. Much of the emphasis is on mental illness and on the social agencies that cope with persons labeled mentally ill. Although the authors acknowledge a special debt to Thomas Szasz and *The Manufacture of Madness* (1), this book is much more than a simple extension of Szasz's views. It is an unusually comprehensive, clear, and well-balanced introduction to a sociological perspective on deviance that challenges conventional psychiatric theory and practice. It should be read by any psychiatrist who wishes to learn what sociological research has to say about the social "creation" of "mental illness."

The first four chapters constitute a lucid introduction to basic concepts and theories in the sociological study of deviance. Thus Hawkins and Tiedeman begin with a sophisticated discussion of rules, roles, and labeling theory, not only within the more traditional symbolic interactionist approach of Becker, Goffman, and Scheff but in the radical emergent subfield of ethnomethodology as well. Their treatment of this sometimes arcane approach is clear and useful, touching on the central ethnomethodological issues of how human beings construct and maintain the sense and appearance of social order (as in the work of Garfinkel) and on practical applications of such an approach (as in the work of Cicourel and Douglas). Much of this conceptual and theoretical background relates directly to mental illness, as can be seen in the authors' central assertion that the sources of mental illness and, more generally, of deviance reside in social processes that create labels rather than in bodies that become ill. The assertion is hardly new, but a book that assembles the concepts and the existing data in one place is both new and valuable.

The remainder of the book deals with what the authors call "social-control" agencies that process, house, and otherwise deal with persons who have been labeled deviant. Much of this material—from Goffman's total institution to Rosenhan's studies of psychiatric inpatient facilities—will be familiar, but some of it, especially that dealing with criminality and justice, will be less so. In all, this section is less creative than the earlier one, but it is relevant to the psychiatric enterprise, and it will repay careful reading. A final chapter considers the broader role and function of deviance in society. Even though the authors' treatment of the many complex issues involved in this topic is brief, they manage to convey some of the importance that such a societal perspective can yield.

Few books are at once clear, judicious, and sophisticated. This one is. It can be read with profit by students and professionals alike. The labeling theory that the authors review and extend is at times conceptually muddled, and it sorely wants for careful empirical test. In time, much of it will no doubt prove to be illusory. Nevertheless, the perspective must be taken seriously. Hawkins and Tiedeman should be congratulated for producing a book that will help the reader to do exactly that.

The Inner World of Daydreaming, *by Jerome L. Singer. New York, N.Y., Harper & Row, 1975, 261 pp., $10.00.*

Although this book was designed, according to the author's own statement, for a general audience, it can have a number of uses for psychiatrists. Pleasantly written, it might make a bibliotherapeutic tool for those who use this adjunct mode. The volume can certainly be easily read in an evening or scanned in chunks at a number of starting points. For those reviewing the use of directed fantasy in psychotherapy or considering this strategy for the first time, the book provides a good entry point and guide. The second half, in particular, reports on a number of studies in the area painlessly enough to hold a casual reader's attention and artfully enough to evoke curiosity in the more sophisticated.

The ability to write fluently for a lay audience on a subject like fantasy is a challenge often vouchsafed only to professionals who possess a vast and profound knowledge and the capacity to distill it. Informed readers may be irritated by Singer's reminiscences of his own "daydreams" or his analysis of Scarlet O'Hara's daydreams or object to the rehashing of Erikson's version of Ben Roger's steamboat fantasy from *Tom Sawyer* or the discourse on why people close their eyes when kissing. In fact, the material is perhaps more chatty than necessary, but the book's organization is coherent. The sophisticated reader can therefore easily turn to other sections when bored. However, there are disquieting nuances of a Masters and Johnson how-to-do-it approach to daydreaming that are not easily dismissed.

For the more serious, a better grasp of Singer's scope will come from an examination of his technical work (1). His article for the *American Scientist* (2) is likely to be more satisfactory than his more specifically targeted articles, e.g., those on daydreaming and laterality of eye movements, women's fantasies during sexual intercourse, and television viewing habits of pre-school children. Two articles currently in press promise more usefulness for the specific concerns of psychiatrists. One deals with daydream patterns and self-awareness in psychiatric patients (*Journal of Nervous and Mental Disease*) and the other with a factor analytic study of daydreaming and symptom patterns of psychiatric patients (*Journal of Abnormal Psychology*).

As a guide to encourage self-observation in patients, as a relaxed vehicle for review, or (especially in the latter chapters) as a palatable compilation of some recent research findings by a bona fide authority in the field, the book is worthy of attention.

Developments in Human Services, Vol. II, *edited by Herbert C. Schulberg, Ph.D., and Frank Baker, Ph.D. New York, N.Y., Behavioral Publications, 1975, 374 pp., $17.95; $13.95 (paper).*

This second volume of an ambitious project conceived by the editors as a series on developments in human services consists of an introduction titled "Social Values, Economic Influences and Integrated Human Services," written by the editors; part 1, "Developing Program Models for the Human Services," by Mark A. Lawrence, M.D.; part 2, "The Economics of Human Services," by Gerald Rosenthal, Ph.D.; and part 3, "Developing Human Services in New Communities," by Donald C. Klein, Ph.D.

I would suggest that one read the preface before perusing this volume, even before reading the introduction, to appreciate the comprehensive goals of the editors, to understand the format of the volumes and their parts, and to anticipate the editors' plans for publishing in-depth discussions and reviews on human service topics in the future. The preface is included in each of the three parts because each is available as a separate publication.

The introduction offers an overview of the problems confronting human services planners and also discusses the trends in economic factors, manpower utilization, and program patterns.

Dr. Lawrence presents an extensive discussion of developing program models for the human services, including health and mental health subsystems. He carries on the discussion to include an idealized systems model and attempts to predict future developments in the delivery of human services.

Dr. Rosenthal discusses the economics of human services, emphasizing the need to reach optimal benefits that are derived from the use of our limited resources. Research is discussed throughout the book as an integral function of services. However, I doubt that the essential importance of research in order to understand and evaluate the trends, the emerging innovative programs, and the effectiveness of delivery of services is given adequate emphasis. I cannot agree with the following position expressed by Dr. Rosenthal:

> However, when resources are scarce, reducing the limitations of technology is also a resource-using activity. It needs to be weighed against the other uses to which resources could be put. Decisions to invest in research as opposed to service provision in human services embody this type of tradeoff between alternatives. Each time we devote medical manpower to research we reduce the supply of physicians for providing medical care services. Whether or not this is a good thing to do depends on our expectations with regard to the future benefit from the research as compared to the present opportunity cost in lessened availability of services. (p. 179)

I can only emphasize my belief that research and evaluation are essentials in every human services delivery system. Without adequate research and evaluation, valuable improvements and successful programs could eventually turn to disillusionment and failure or, even worse, inhibit future experimental approaches to human services, including health and mental health delivery systems.

Dr. Klein discusses the development of human services in a new community. This portion of the volume is particularly valuable to those confronted with the planning of human services in newly developed communities or those with a beginning recognition of the need for human services.

This is an important volume containing a valuable contribution to our understanding of the complexities of forces affecting human services, the changing nature of health and mental health services, and the critical need for planning for the future. It is equally helpful to those newly entering and those already active in the field of human services. There is an excellent index and extensive references.

We can look forward to the future volumes planned by the editors.

Decatur, Ga.

The Disabled and Their Parents: A Counseling Challenge, *by Leo Buscaglia, Ph.D. Thorofare, N.J., Charles B. Slack, 1975, 392 pp., $8.95.*

Dr. Buscaglia performs in this book the much needed task of chiding members of the helping professions for their insensitivity and pomposity in counseling the disabled and their parents. Most professionals who deal with the disabled have not given sufficient consideration to the possibly harmful effects of stereotyped classifications and austere advice on perplexed, confused, and lonely parents. Not only does the book chide us for our callousness, it also clearly delineates how counseling the disabled and their parents can be made more effective.

Dr. Buscaglia speaks feelingly of the cruelty of clinical detachment. He pays less attention to the cruelty of artificially appropriate attitudes in therapists and parents. He points out that the cruelty of unwarranted expectations often has greater impact on the demander than the demandee and that the parent may be hurt more than the child. It is not enough, however, to learn to refrain from demanding. The unloving parent does not become more loving by practicing the right approaches. To become more loving the parents may have to seek extensive therapy for themselves or subject themselves to other influences for change.

Although the book cautions the divine therapist to be more human, it also expects the human disabled person to be more divine. The models held up in the book for the disabled person to follow are Horatio Alger-like figures who have unfailingly conquered adversity. Although he talks of negative affects present in the disabled, Dr. Buscaglia speaks mainly of such negative feelings as hurt and sadness rather than scorn or tyranny. The sentimentality of assuming that the disabled are less capable of bitterness, bitchiness, and contempt than the average individual is not really helpful.

The disabled can less afford to smugly warm themselves over the rightness of their feelings than the able bodied. They are as much entitled to the dubious privilege of being depressed as is the rest of the population. Positive thinking may not be the essential ingredient of any prescription for

the disabled. Is a negative, cynical view of the world permissible only for the nondisabled? If the disabled are encouraged constantly to pass all of the courses that society provides, they may miss other opportunities for development that might in some respects be more fulfilling for them, e.g., there are no societal courses on how to become a Toulouse-Lautrec. A necessary ingredient for the full development of the individual is not only love but some decent distance. We have not learned to balance love and distance sufficiently well to encourage the creativity and productivity of the Toulouse-Lautrecs and, at the same time, develop the capacity for fulfilling social relationships.

Dr. Buscaglia presents a contradiction in encouraging us to be both euphemistic and honest. He does not indicate how one determines when to be one and when to be the other. It is necessary to know when euphemism is tactful and when it is timid and when honesty is arrogant and when it is humble. It is not, as Dr. Buscaglia states, a general rule that the disabled neither crave nor need oversolicitude, pity, or special social considerations. Some if not most of them crave all of these forms of attention and at times may need preference. The problem is not that they crave too much but that they be accepted as readily as other human beings who ask too much for themselves.

Dr. Buscaglia does well to remind us of the very human needs of the disabled in a world that has become increasingly fund oriented and parochial rather than service oriented and global. It is not likely that the disabled will receive the attention they deserve until we recognize that to provide them with the same opportunities as the able bodied is justifiably much more expensive.

IRVING MARKOWITZ, M.D.
Orange, N.J.

Review of Child Development Research, Vol. 4, *edited by Frances Degan Horowitz, E. Mavis Hetherington, Sandra Scarr-Salapatek, and Gerald M. Siegel. Chicago, Ill., University of Chicago Press, 1975, 654 pp., $17.50.*

The purpose of this book, according to the editors, is "to bring together a set of chapters that would offer a review and integration of what is and what is not known about current topics and issues." This volume is composed of 11 chapters. The first 2 deal with genetics in some detail. One concerns itself with the development of intelligence and points out that we still know very little about the sources of intellectual variance within disadvantaged populations. It also emphasizes the importance of genetic sources of variation. The second deals with genetic abnormalities in development and describes a number of conditions in which genetics have a primary etiological role.

In the next chapter, "The Development of Behavioral Competence in Infancy," the author states that although this field is expanding rapidly, there is much work to be done. The chapter on "Reproductive Risk and the Continuum of Caretaking Casualty" addresses itself to problems of prenatal, perinatal, and postnatal problems and their influence on the development of the child. The next chapter deals with abused children.

The following chapter is essentially a review in which the author points out, among other things, that videotape has replaced the audio tape recorder and gives much more substantive information about the process of language development. The author of the next chapter, "The Development of Referential Communication Skills," states that "the prospects for the future depend very heavily on our success in integrating our conceptions of communication process within our conceptions of language."

The next chapter, "Drug Treatment of Children with Behavior Problems," points out the lack of critical analysis in the literature on this topic. It also warns against the excessive use of drugs in the treatment of children with learning disabilities and minimal brain damage.

Behavior modification is the topic of the next chapter. This author gives over a considerable amount of space to some of the inadequacies of the research methodology in behavior modification as an educational technique. The chapter on "Parent-Child Relations" deals with the development of aggressive behavior and how it is related to parental punitiveness and nonacceptance as well as to parental permissiveness and laxity.

Chapter 10, "Intellectual Development During Adolescence," points out the need for better focused and formulated research. The last chapter, "Cognitive Development in Cross-Cultural Perspective," indicates some of the weaknesses of research to date. Some of the newer research looks promising, but further work needs to be done.

This book contains as many things we do not know as those we do. Each author covers his topic thoroughly, almost redundantly at times. There is real "meat" in every chapter, but one wonders if some of it could have been condensed. For the reader who wishes to delve deeply into the various aspects of child development and research, this is a voluminous and commendable book. It has the added attraction of a concise review of the chapters at the end of each section. It is interesting to note after each painstaking review of the literature how much we have yet to learn in each of the areas covered.

This book is to be recommended to the serious reader in medicine, psychology, social work, and education and to other child-oriented students. It could also serve well as a reference book.

STUART M. FINCH, M.D.
Tucson, Ariz.

Opening the Door: A Study of New Policies for the Mentally Handicapped, *by Kathleen Jones, with John Brown, W.J. Cunningham, Julian Roberts, and Peter Williams. Boston, Mass., Routledge & Kegan Paul, 1975, 251 pp., $20.75.*

This study by Kathleen Jones and her coworkers is based on a careful in-depth evaluation of the residential and community facilities available in one of England's provincial districts, an area belonging to 1 of 14 regional hospital boards. Based on their evaluation, the authors make a number of recommendations. They describe the improvements made in the last decade but also stress the weaknesses observed in the institutions and criticize the lack of programs in the communities. It is easy to say, "Open the doors," but where do these doors lead?

In the preface Jones, Professor of Social Administration at the University of York, states, "Why yet another survey? In the first stage of the work we were repeatedly asked this question by the staff at all levels. . . . It was not surprising that they felt they had had enough good advice; they simply wanted to be left to get on with the job." But there was a difference in the new approach of this team of sociologists. Instead of working as "sociologists, reformers and adminis-

trators" had previously done—"de haut en bas"—they proceeded in the "more empirical and inductive approach" rather than "from abstract principles and working downwards." Although the authors concede that this approach has "its limitations and is more modest in scope and intention," they add that "it may be more securely based, for it offers real possibilities of change with staff cooperation." I wholeheartedly agree.

In discussing the policy background, which is applicable to the American scene only in part even though many problems are shared, Jones indicates that "as the battle for reform moves from central to local government, it becomes more diversified, more fragmented, more difficult to command" and that it "may easily degenerate in dozens of local squabbles."

The authors describe the shortcomings in clear prose that is well documented in its details and illustrated by examples of the experiences of individual team members. When suggesting solutions and outlining staff needs in all professions (including general medical and psychiatric fields) and the development of community facilities, they try to avoid the gap between "idea (models, blueprints) and reality." It is a pleasure to read a well-balanced study after having worked through innumerable sermons about what models one should follow, sermons that usually overlook the main problem, i.e., the needs of the patient.

This book may not interest the general psychiatrist. However, the psychiatrist who has an interest in the field of mental retardation, particularly one who is even tangentially involved in planning for the mentally retarded, can profit a great deal from the approach outlined by this group of sociologists. Even if one may not agree with each conclusion or recommendation, one can learn a great deal from this book. It is highly recommended to our community, state, and federal "planners" in this area of human suffering.

BENEDICT NAGLER, M.D.
Lynchburg, Va.

Group Psychotherapies for Children: A Textbook, *by S.R. Slavson and Mortimer Schiffer. New York, N.Y., International Universities Press, 1975, 467 pp., $17.50.*

The activity of play is a universal form of expressive behavior. It is common to all and to every stage of life. It stimulates movement and perception while encouraging relatedness in an acceptable and manageable form. It recruits imagination and fantasy in behalf of reality and often helps make reality tolerable and pleasurable. Play provides the opportunity to reproduce experiences with the potential for success, making it a positive learning experience. It permits identification with many varied activities while promoting experimentation with all aspects of living. It thus becomes a window to the world for the child. No wonder it has become a major instrument in our approach to helping children cope with their problems.

S.R. Slavson is a pioneer in the application of some of the principles of play to the treatment of groups of children. He has reported his experiments with a variety of techniques in a series of writings over the past 40 years. *Group Psychotherapies for Children*, coauthored by Slavson and Mortimer Schiffer, presents a fine summation of Slavson's contribution to the field of psychotherapy of children. Much of its content will be familiar to those who have followed his work. The format of the text is highly organized and well structured so that professionals wishing to acquaint themselves with Slavson's theories and practices will have little difficulty. Much of Slavson's approach to the subject is presented in a concrete, didactic manner that blends theory and practice.

The book is organized in four parts: Activity Group Therapy, Activity-Interview Group Psychotherapy, Play Group Therapy, and Therapeutic Play Groups in Elementary Schools. These divisions seem to be well defined at first glance; however, close examination of the procedures and categories within each technique shows that much is left to be desired.

Activity group therapy (AGT) is presented as specific for primary behavior disorders, a classification of childhood disturbance that is no longer in use. The other techniques are presented as specific for other equally poorly defined categories of patients. This raises a serious question of their applicability because these techniques are predicated on their specificity to patient groups. As one examines the indications and counterindications for ATG and the other techniques, the issues of selectivity of types of patients become even more obscure because of the overlapping of so many of the treatable and untreatable categories listed by the authors. One can account for success and failure without difficulty by simply challenging the diagnostic classifications of the treated patients. It is this very issue which has made the assessment of therapeutic effectiveness such a problem in all forms of therapy. However, Slavson and Schiffer state, "The effectiveness of AGT is in direct relation to the care taken in selecting and grouping children correctly" (p. 111).

Another problem plaguing so much of the work in the field of child psychiatry is present in this book—the use of special language. Such terms as "instigators," "neutralizers," and "neuters" are coined for this text. Behavior within the group is identified with "true focus of infection" and "pseudo focus of infection." Relationships within the group are presented as "symbiotic" or "anaclitic." This specialized use of terms, even when definitions are offered, makes it difficult to transpose both theory and practice into any other frame of reference. This style contributes to a subtle egocentricity, permitting such questionable statements as "A considerable body of clinical material has been accumulated over a period of almost four decades to establish that group therapy is the major treatment modality for children" (p. 133). However, in spite of this, the authors describe many good and sound principles for planning, intake, management, record keeping, and termination practices. These descriptions make the book a valuable addition to the body of literature on the psychotherapy of children.

The second part of the book, on activity-interview group psychotherapy (A-IGP), presents the well-defined but arbitrary criteria distinguishing this form of therapy from AGT. Children with "uncontrollable aggression, autism, psychosis, brain damage" or "severe sibling rivalry, affect hunger, psychopathic trends and devoid of impulse control" are all excluded as candidates for A-IGP. This would serve to exclude a majority of the children now being seen in many psychiatric facilities and raises some serious questions about the selectivity often demonstrated by professionals attempting to fulfill their responsibility for caring for those needing help. Is this selectivity based on the highly specialized nature of such techniques as A-IGP or does it reflect the inappropriateness of many of our classifications and techniques?

This book does us a service by definitely presenting criteria for patients, therapists, and procedures. The achievement or lack of achievement of these criteria should make all

of us question ourselves as well as the authors. Within their assessment of the dynamics of the treatment relationship, Slavson and Schiffer present the therapist as "the ideal human." Can we approach this state without critically assessing what we are doing in the name of therapy?

In the third section, play group therapy (PGT) is defined as "an analytic form of group treatment employed with preschool children approximately four to six years of age." This kind of definition characterizes much of the construction of this book. It lends an Alice in Wonderland quality, i.e., saying it is so makes it so. The section itself has many fine descriptions of play and its meanings, but certainly these meanings and their application should not be limited to the narrow spectrum of the four- to six-year-old. Much of this section can be applied to both individual and group therapy with children of all ages.

The final section of the book raises the interesting question of how to distinguish between that which is therapeutic and that which is therapy. In my opinion, all play contains therapeutic elements, but helping children to play within groups does not make all play groups therapeutic. Therapy must always include definition by diagnosis, identification of need and conflict, and interventions directed toward these purposes. Whether this can take place within a school setting, where the main objective is to teach, is open to question.

This book raises as many questions as it answers by its approach to its subject. Read with a critical eye, it presents many challenges to those who would treat children with the techniques it describes.

SOL NICHTERN, M.D.
New York, N.Y.

Death and Neurosis, *by Joachim E. Meyer; translated by Margarete Nunberg. New York, N.Y., International Universities Press, 1975, 147 pp., $8.50.*

Meyer explores the relationship between conflicts and predispositions concerning mortality and the development of neuroses to handle these anxieties. He approaches this relationship by considering human reactions to death at the time of dying, to dying alone, and to thoughts of the hereafter. That man is future oriented is one of his assumptions; he also assumes that one of the major factors contributing to conflict is an awareness of approaching death before achievement or completion of an individual's life goal and/or mission.

Two means of coping with phenomena and events are presented: the concept of *attention voluntaire*, defined as a reactive readiness to deal with anything, and *attitude speculaire passive*, defined as not looking for any action to deal with a specific occurrence. Both modes of response enable a person to minimize anxiety about death to the point where he or she can react appropriately. In Meyer's opinion, anxiety is thus a barrier to coping, although anxiety can be an appropriate response so long as its intensity is not crippling and it does not interfere with reasonable and effective coping patterns.

Meyer also states that anxiety is generated by awareness of death, which is in turn minimized by "familiarization"; this term is never defined. He uses the old active-passive perspective based on the belief that fear of death stems from the inability to observe one's own death as a spectator. In my opinion this perspective is not useful because it fails to actually describe anything and because most people have thrown away the concept in favor of a theory that accounts for environmental and social as well as individual psychodynamics.

The author points out that Freud believed death did not exist in the unconscious; later he contests this position (and rightly so). For Meyer, fear of death is basic to other fears—separation anxiety, castration fear, and guilt. He reviews concepts of anxiety in general, then in terms of separation, castration, fear of love (death anxiety at the time of orgasm), and moral anxiety. He also discusses types of neuroses, such as cardiac phobia and other phobias and obsessive-compulsive neuroses.

Meyer excludes several important factors, such as age and religious philosophy, from his review of potential causes of attitudes toward death. He also fails to note anxiety resulting from a real or imagined threatened loss of control and anxiety arising out of a sense of impotence or loss of self-determination due to lack of social power or decision-making influence. This kind of death anxiety—fear of the death of one's individuality—is one of the most predominant. However, Meyer does mention that neurosis becomes a defense against anxiety resulting from a sense of annihilation of the person. He also states that suicide would occur if the person failed to bind anxiety. He does not satisfactorily account for suicide as a means of asserting potency, such as suicide by persons with terminal illnesses; aggression is not the only factor in suicide. Also, he discusses anxiety neurosis only in terms of a real fright trauma. The discussion of fright depersonalization as anticipation of death ignores its use as a defense to preserve the ego from being overwhelmed by anxiety.

The most valuable chapter in this book, "Neuroses in the Second Half of Life," views neuroses in senescence as exaggerations of character traits developed in early years. Another chapter, "Psychodynamic Aspects—Provisional Conclusions and Discussion," is written with great clarity and specificity. The relationship between neurosis and fear of death is summarized skillfully, although it involves some rehashing of earlier chapters. In "Current Conscious Attitudes Toward Death and Dying," Meyer comments that the movement away from religion has brought about some additional freedom from concern about death, primarily from the standpoint of the hereafter. He questions (with wisdom, in my opinion) whether or not this movement has actually given freedom or has generated even greater, although different, fears.

The final chapters of this book discuss death from philosophical, historical, and anthropological standpoints and depart from the main theme and thesis of the book. Although these sections offer a deeper perception and more evidence, they do not really contribute to the book's stated topic.

Perhaps the reason that the book is difficult to read stems from its translation from German into English. It seems almost to have been written in two parts: the opening chapters with much difficulty and confusion and the latter part with greater clarity and more specific references from thanatology. I feel that the section on suicide is weak, consisting of dubious theory with no clinical or empirical data to back it up.

I would not recommend this book highly; there are others better written and offering more worthwhile material.

Highlights of the 129th Annual Meeting

THE 129TH ANNUAL MEETING of the American Psychiatric Association, which focused on the theme "The Continuing Revolution," was held in Miami Beach, Fla., May 10–14, 1976. The total registration was 9,181, including 4,075 members, 4,204 nonmembers, 804 scientific exhibitors, 98 members of the press, 408 program participants, and 2,641 spouses and families of members.

The opening session, on Monday morning, May 10, was brought to order by Judd Marmor, M.D., 104th President of the Association. Official greetings were extended by the Honorable Stephen P. Clark, Mayor of Dade County, and the Honorable Harold Rosen, Mayor of the City of Miami Beach.

Dr. Marmor introduced Dr. Robert E. Jones, Associate Medical Director, Institute of the Pennsylvania Hospital, Philadelphia, Pa., and Chairperson of the Benjamin Rush House Committee. Dr. Jones described progress on the Benjamin Rush National Park in Philadelphia, to which the Association has been the largest contributor. In recognition of this contribution, Dr. Jones presented the Benjamin Rush Gavel to Dr. Marmor to be placed in the American Psychiatric Association Museum. Dr. Marmor then introduced Mr. Franklin Roberts, producer of a one-act play depicting scenes from the life of Benjamin Rush, "The Revolution Is Not Over," presented at the opening session through the courtesy of Merck Sharp & Dohme.

Following the play, Dr. Marmor introduced the distinguished guests, who included the following: Prof. W. Linford Rees, President of the Royal College of Psychiatrists and Treasurer of the World Psychiatric Association; Dr. Peter A. Martin, President of the American College of Psychiatrists; Dr. Irving N. Berlin, President of the American Academy of Child Psychiatry; Dr. Walter Goldschmidt, President of the American Anthropological Association; Dr. Gerald J. Sarwer-Foner, President of the American Academy of Psychiatry and the Law; Dr. Earl G. Witenberg, President of the American Academy of Psychoanalysis; Dr. Michael Shepherd, Professor of Epidemiology, Psychiatric Institute, University College Hospital, London; Dr. Milton Greenblatt, President of the American Board of Psychiatry and Neurology and President of the American Association for Social Psychiatry; Dr. Douglas D. Bond, President of the American College of Psychoanalysts; Dr. Jere W. Annis, Vice-Chairman of the American Medical Association's Board of Trustees; Dr. Bernice Sachs, Past President and representative of the American Medical Women's Association; Dr. Herbert S. Gaskill, President of the American Psychoanalytic Association; Dr. Tsung-yi Lin, President of the World Federation for Mental Health; Dr. Wilbert J. McKeachie, President of the American Psychological Association; Dr. Albert J. Silverman, President of the American Psychosomatic Association; Dr. Gustavo A. Lage, President of the American Society for Adolescent Psychiatry; Mr. George Blank, representing the Association of Mental Health Administrators; Chaplain Joseph B. Brady, President of the Association of Mental Health Clergy; Dr. Jean Baptiste Boulanger, President of the Canadian Psychiatric Association; Dr. Henry Podlewski, First Vice-President of the Caribbean Psychiatric Association; Dr. R. Kusumanto Setyonegoro, representing the Indonesian Psychiatric Society; Mr. Sheldon R. Goldstein, Executive Director of the Florida Chapter of the National Association of Social Workers; Dr. Walter H. Wellborn, Jr., President of the National Association of Private Psychiatric Hospitals; Ms. Ruth Lewis, Coordinator for Psychiatric and Mental Health, American Nurses' Association; Dr. Rene Gonzalez, representing the World Health Organization in his role as Regional Advisor in Mental Health, WHO-Pan American Health Organization; Dr. Howard P. Rome, President of the World Psychiatric Association; and Dr. Ruben Hernandez Serrano, General Secretary of the Venezuelan Psychiatric Society and the College of Physicians of the Miranda State University, Caracas.

Dr. Marmor then called on Prof. W. Linford Rees, who commented on the plans for the VI World Congress of Psychiatry (which the Association is cosponsoring), to be held in Honolulu, Hawaii, August 29–September 3, 1977. Dr. Tsung-yi Lin, President of the World Federation for Mental Health, extended an invitation to the Federation's World Congress on the theme "Today's Priorities in Mental Health," which will be held in Vancouver, B.C., Canada, August 21–26, 1977.

Dr. Marmor extended the Association's appreciation to Dr. Peter Martin and the Program Committee for their excellent work. Dr. Martin noted that this year for the first time there was a specific program for spouses within the scientific program and mentioned the availability of continuing education courses for AMA Category I credit. Dr. Marmor then welcomed Ronald A. Shellow, M.D., Co-Chairperson, Lo-

cal Arrangements Committee, who extended an invitation to a Latin fiesta at the close of the annual meeting.

Vice-President Daniel X. Freedman, M.D., presented Dr. Marmor, who gave an eloquent address on "Psychiatry 1976—The Continuing Revolution." Vice-President Jack A. Wolford, M.D., introduced Robert W. Gibson, M.D., who responded thoughtfully as the President-Elect. (The texts of these addresses are published elsewhere in this issue of the *Journal*.)

The opening session closed with organ music by John E. Fryer, M.D. Dr. Marmor adjourned the meeting with an invitation to a reception held by the officers of the Association immediately thereafter.

SCIENTIFIC SESSIONS

The scientific sessions began Monday afternoon, May 10, There were 321 papers presented in regular sessions, as well as 30 papers on new research presented in several sessions throughout the week. There were 86 morning panels and 59 evening panels, 7 videotaped sessions, and 35 films in 14 sessions.

The Solomon Carter Fuller Lecture, "Toward a Second American Revolution," was given by John Hope Franklin, Ph.D., Chairman, Department of History, University of Chicago. Michael Shepherd, M.D., Professor of Epidemiology, Psychiatric Institute, University College Hospital, London, gave the Adolf Meyer Lecture, "The Life and Works of Sir Aubrey Lewis." Jaime Benitez, Resident Commissioner, Office of the Commonwealth of Puerto Rico, Washington, D.C., gave the Simon Bolivar Lecture, "Toward Understanding the Historical Role of Latin America and Puerto Rico in Its Relation with the United States: A Perspective for the Future." The Benjamin Rush Lecture, "The Significance of Boundaries in Nineteenth-Century American Experience," was given by David Brion Davis, Ph.D., Professor of History, Yale University, New Haven, Conn. The Seymour Vestermark Memorial Lecture, "The Function of Participation as a Learning Teaching Process," was presented by Raquel E. Cohen, M.D., Associate Professor of Psychiatry, Harvard Medical School, Boston, Mass. There were 5 special lectures: "Psychoanalysis and Historical Analysis," by Elizabeth Fox-Genovese, Ph.D., Assistant Professor of History and Liberal Arts, University of Rochester, Rochester, N.Y.; "A Bicentennial Lecture: Benjamin Rush and Those Who Came After Him," by Francis J. Braceland, M.D., Editor, *American Journal of Psychiatry*, and Senior Consultant, Institute of Living, Hartford, Conn.; "Life, Liberty, and Philippe Pinel," by Dora Weiner, Ph.D., Associate Professor, Department of History, Manhattanville College, Purchase, N.Y.; "In Praise of the Cognitive Emotions," by Israel Scheffler, Ph.D., Victor S. Thomas Professor of Education and Philosophy, Harvard University, Cambridge, Mass,; and "Fear of Success," by Martina S. Horner, Ph.D., President, Radcliffe College, Cambridge, Mass.

BUSINESS SESSION

The business session was convened as a meeting of the Assembly of District Branches acting for the membership in receiving reports of the officers and actions of the Board of Trustees. The meeting was held on Tuesday, May 11, in the South Hall of the Miami Beach Convention Center. Dr. Marmor presided. After a memorial to deceased Fellows and members, Henry Brosin, M.D., presented a brief tribute to the contributions of Dr. Malcolm Farrell, a former Speaker of the Assembly of District Branches, who died August 5, 1975.

Eugene A. Hargrove, M.D., Chairperson, Committee of Tellers, recorded the results of the election of officers and trustees and of the vote on the proposed amendments to the Constitution and By-Laws. There will be a run-off election between Frank Ayd, Jr., M.D., and Jack Weinberg, M.D., for the office of President-Elect. A run-off election will also be held for the office of Vice-President (to serve a term of two years); the two candidates are Alan A. Stone, M.D., and Jack A. Wolford, M.D. Charles B. Wilkinson, M.D., was certified as Treasurer; Nancy C.A. Roeske, M.D., as Trustee-at-Large; William B. Spriegel, M.D., as Area IV Trustee; and David Starrett, M.D., as Area VII Trustee. A run-off election will be held between Lane Ameen, M.D., and Ben W. Feather, M.D., for Area I Trustee. In addition, the Committee of Tellers certified the approval of amendments to the following sections of the Constitution and By-Laws: Chapter 3, Section 3; Chapter 8, Section 5; Chapter 9, Section 1; and Chapter 10, Section 1. The report of the Committee was accepted. Two referenda by petition were also certified approved.

The reports of the officers to the membership followed. (The floor was open to questions following each report, and all reports were accepted as read by the Assembly.) Jules H. Masserman, M.D., summarized his 26-page Secretary's report, which included the principal actions of the Board of Trustees and of the Executive Committee. Jack Weinberg, M.D., gave the report of the Treasurer, and Miltiades L. Zaphiropoulos, M.D., gave the report of the Speaker of the Assembly of District Branches. Irwin N. Perr, M.D., J.D., spoke as Speaker-Elect. Kent Ravenscroft, Jr., M.D., Chairperson of the Committee on Constitution and By-Laws, reported on the Committee's work on proposed revisions of the Constitution and By-Laws in accordance with the mandates of the Key Conference. Laura E. Morrow, M.D., presented the report of the Membership Committee. Melvin Sabshin, M.D., presented the report of the Medical Director.

Dr. Marmor then presented plaques to Dr. Zaphiropoulos, the retiring Speaker, and to Jack A. Wolford, M.D., the retiring Vice-President. John P. Spiegel, M.D., presented the President's Badge to Dr. Marmor.

Dr. Marmor then adjourned the business session and called the annual forum to order. A question related to the desire for more sessions at the annual meeting qualifying for AMA Category I credit was referred to Dr. Henry Work, who reported that the Council on Medical Education and Career Development and the Program Committee plan substantial efforts in this area at forthcoming meetings. Dr. Marmor then adjourned the annual forum.

MEETINGS OF THE BOARD OF TRUSTEES

The Board of Trustees met in regular sessions on Sunday, May 9, and Thursday, May 13. Transactions will be reported by the Secretary.

CONVOCATION

The 20th Convocation of Fellows was held in the Grand Ballroom of the Fontainebleau Hotel on Wednesday, May 12. Dr. Marmor presided. After the processional march, Dr.

Marmor called the convocation to order. The Life Fellows were inducted by Robert Gibson, M.D., President-Elect.

Life Fellows and life members who have been in the Association for 50 years (1926–1976) were introduced by Dr. Marmor. They are S. Spafford Ackerly, M.D., Louisville, Ky.; Leo H. Bartemeier, M.D., Baltimore, Md.; Eugene N. Boudreau, M.D., Syracuse, N.Y.; Betsy Coffin, M.D., Detroit, Mich.; Laurence Martin Collins, M.D., Convent Station, N.J.; Olive Alfreda Cooper, M.D., Springfield, Mass.; John Morris Dorsey, M.D., Detroit, Mich.; Joseph Epstein, M.D., New York, N.Y.; Harry Goldsmith, M.D., Baltimore, Md.; Emmett Francis Hoctor, M.D., Farmington, Mo.; Nolan D.C. Lewis, M.D., Frederick, Md.; Alva Gwin McCord, M.D., Albany, N.Y.; Curtis Tuttle Prout, M.D., Orleans, Mass,; Baruch Silverman, M.D., Montreal, Que., Canada; Lauren Howe Smith, M.D., Philadelphia, Pa.; and Francis Elwood Weatherby, M.D., Wernersville, Pa.

Dr. Ernst Peter Berner, Vienna, Austria; Dr. John Hope Henderson, Edinburgh, Scotland; Dr. A. Venkoba Rao, Madurai, India; and Dr. R. Kusumanto Setyonegoro, Jakarta, Indonesia, were designated Corresponding Fellows.

The presentation of awards followed. Dr. Marmor presented the Distinguished Service Award—given to APA members "whose distinguished careers have ennobled the profession of psychiatry"—to Ms. Anna Freud, Director, Hampstead Child Therapy Clinic, London, England (Jeanne Spurlock, M.D., accepted the award for Ms. Freud); to Francis J. Braceland, M.D., Editor, *American Journal of Psychiatry*, and Senior Consultant, Institute of Living, Hartford, Conn., and Past President of the Association, 1956–1957; and to Howard P. Rome, M.D., Head, Section on Psychiatry, Mayo Clinic, Rochester, Minn., and Past President of the Association, 1965–1966.

The Lester N. Hofheimer Prize for Research, presented by Marvin Stein, M.D., was given to Joseph Mendels, M.D., Professor of Psychiatry, University of Pennsylvania, Philadelphia, Pa., for a set of related manuscripts covering a range of studies dealing with affective disorders. This award is given to "U.S. research investigators for outstanding accomplishment in psychiatry and mental hygiene."

George E. Gardner, M.D., presented the Agnes Purcell McGavin Award to Eveoleen N. Rexford, M.D., Divisional Professor, Harvard University, Cambridge, Mass., and Eleanor Pavenstedt, M.D., Tiverton, R.I., for "oustanding contributions to the prevention of mental disorders in children."

Eric Plaut, M.D., presented the Robert T. Morse Writers Award to Ms. Lucy Freeman, New York, N.Y., science writer, reporter, and author of 46 popular books. This award honors "popular writers who have made major contributions to the public understanding of psychiatry over an extended period of time."

Alan A. Stone, M.D., Professor of Law and Psychiatry, Faculty of Law and Faculty of Medicine, Harvard University, Cambridge, Mass., received the Manfred S. Guttmacher Award for "an outstanding contribution to forensic psychiatry in the form of a book, monograph, or paper" for his monograph *Mental Health and Law: A System in Transition*, published by the U.S. Department of Health, Education, and Welfare, Washington, D.C., in 1975.

The Seymour D. Vestermark Prize for "outstanding contributions to undergraduate and postgraduate medical education, to continuing education, and to the education of behavioral scientists for research" was presented by Louis A. Gottschalk, M.D., to Raquel E. Cohen, M.D., Associate Professor of Psychiatry, Harvard Medical School, Boston, Mass.

Robert J. Campbell III, M.D., presented the District Branch Newsletter of the Year Award, given "to recognize the overall excellence of outstanding newsletters published by the District Branches of the Association from the standpoint of editorial content, attractiveness of format, and usefulness in furthering communication within the profession," to the Central California Psychiatric Society Newsletter, Don A. Rockwell, M.D., Editor.

The Isaac Ray Award, given to "recognize psychiatrists, attorneys, and judges who have made outstanding contributions to legal psychiatry," was presented by Naomi Goldstein, M.D., to Jonas Robitscher, J.D., M.D., Henry R. Luce Professor of Law and Behavioral Sciences, Emory University School of Law, Atlanta, Ga.

Following the presentation of awards, Dr. Marmor introduced George Wald, Ph.D., Higgins Professor of Biology, Harvard University, the Biological Laboratories, Cambridge, Mass., who gave a scholarly and inspirational address, the William C. Menninger Memorial Convocation Lecture, "Life in the Universe." The Convocation then recessed.

SPOUSES' ACTIVITIES AND ENTERTAINMENT

The Local Arrangements Committee, co-chaired by Ronald A. Shellow, M.D., and Doris Shellow, prepared a schedule of activities that began with a dutch treat welcome party on Sunday night at the Doral Hotel. Other activities included tours of outstanding homes in Miami, the Seaquarium and Parrot Jungle, Palm Beach, and other attractions in the Miami area. There were several opportunities for outdoor activities, including golf and tennis tournaments and sailing and fishing trips. The Starlight Roof of the Doral Hotel was reserved for APA members' enjoyment at a "nightclub evening." The families of APA officers were honored at a champagne brunch at the Fontainebleau Hotel on Tuesday. A cruise dinner-dance was held on Thursday evening. The week's entertainment ended with a Latin fiesta luncheon at the Doral Beach Hotel on Friday, May 14.

ALLIED MEETINGS

The following professional associations also held meetings in or near Miami during the week of May 8–15: the American Academy of Child Psychiatry, the American Academy of Psychiatry and the Law, the American Academy of Psychoanalysis, the American Association of Chairmen of Departments of Psychiatry, the American Association for Social Psychiatry, the American College of Psychoanalysts, the American Society for Adolescent Psychiatry, the American Society for Phenomenological Psychotherapy, the Association of Mental Health Clergy, the Behavior Therapy and Research Society, and the Eastern Psychoanalytic Association.

JULES H. MASSERMAN, M.D.
Secretary, American Psychiatric Association

Coverage and Utilization of Care for Mental Conditions Under Health Insurance —Various Studies, 1973–74

By Louis S. Reed, Ph.D.
Consultant in Health Economics, American Psychiatric Association

This book reports six studies that add to the growing body of data demonstrating the feasibility of covering mental illness under health insurance. Although in some ways it may be considered a supplement to APA's 1972 book **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (Reed, Myers, and Scheidemandel), all of the data are new. The studies cover the following areas:

- Utilization of mental benefits under the Blue Cross and Blue Shield plan for federal employees, documenting that a "plateau" in the use of these benefits was reached in 1973–74.
- Comparison of benefits for mental and other illnesses under selected employee health benefit plans.
- Coverage of mental illness under collective bargaining agreements of selected unions.
- Utilization of care for mental conditions under the Canadian health insurance program, which gives the same coverage for mental as for other conditions.
- Updating of information on Blue Cross benefits for hospital care of mental illness.
- Data from selected Blue Cross and Blue Shield plans on coverage and utilization of mental conditions, with emphasis on major medical coverage.

80pp. Paperbound

Single copy, $4.00; 10–49 copies; $3.80 each; 50 or more copies, $3.20 each.

SPECIAL OFFER: One copy of this book (regular price, $4.00) and one copy of **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (regular price, $6.50) for $8.50.

Tested by time and experience in

1962

"...a considerable decrease of hyperactivity...."[1]
Knobel, 1962

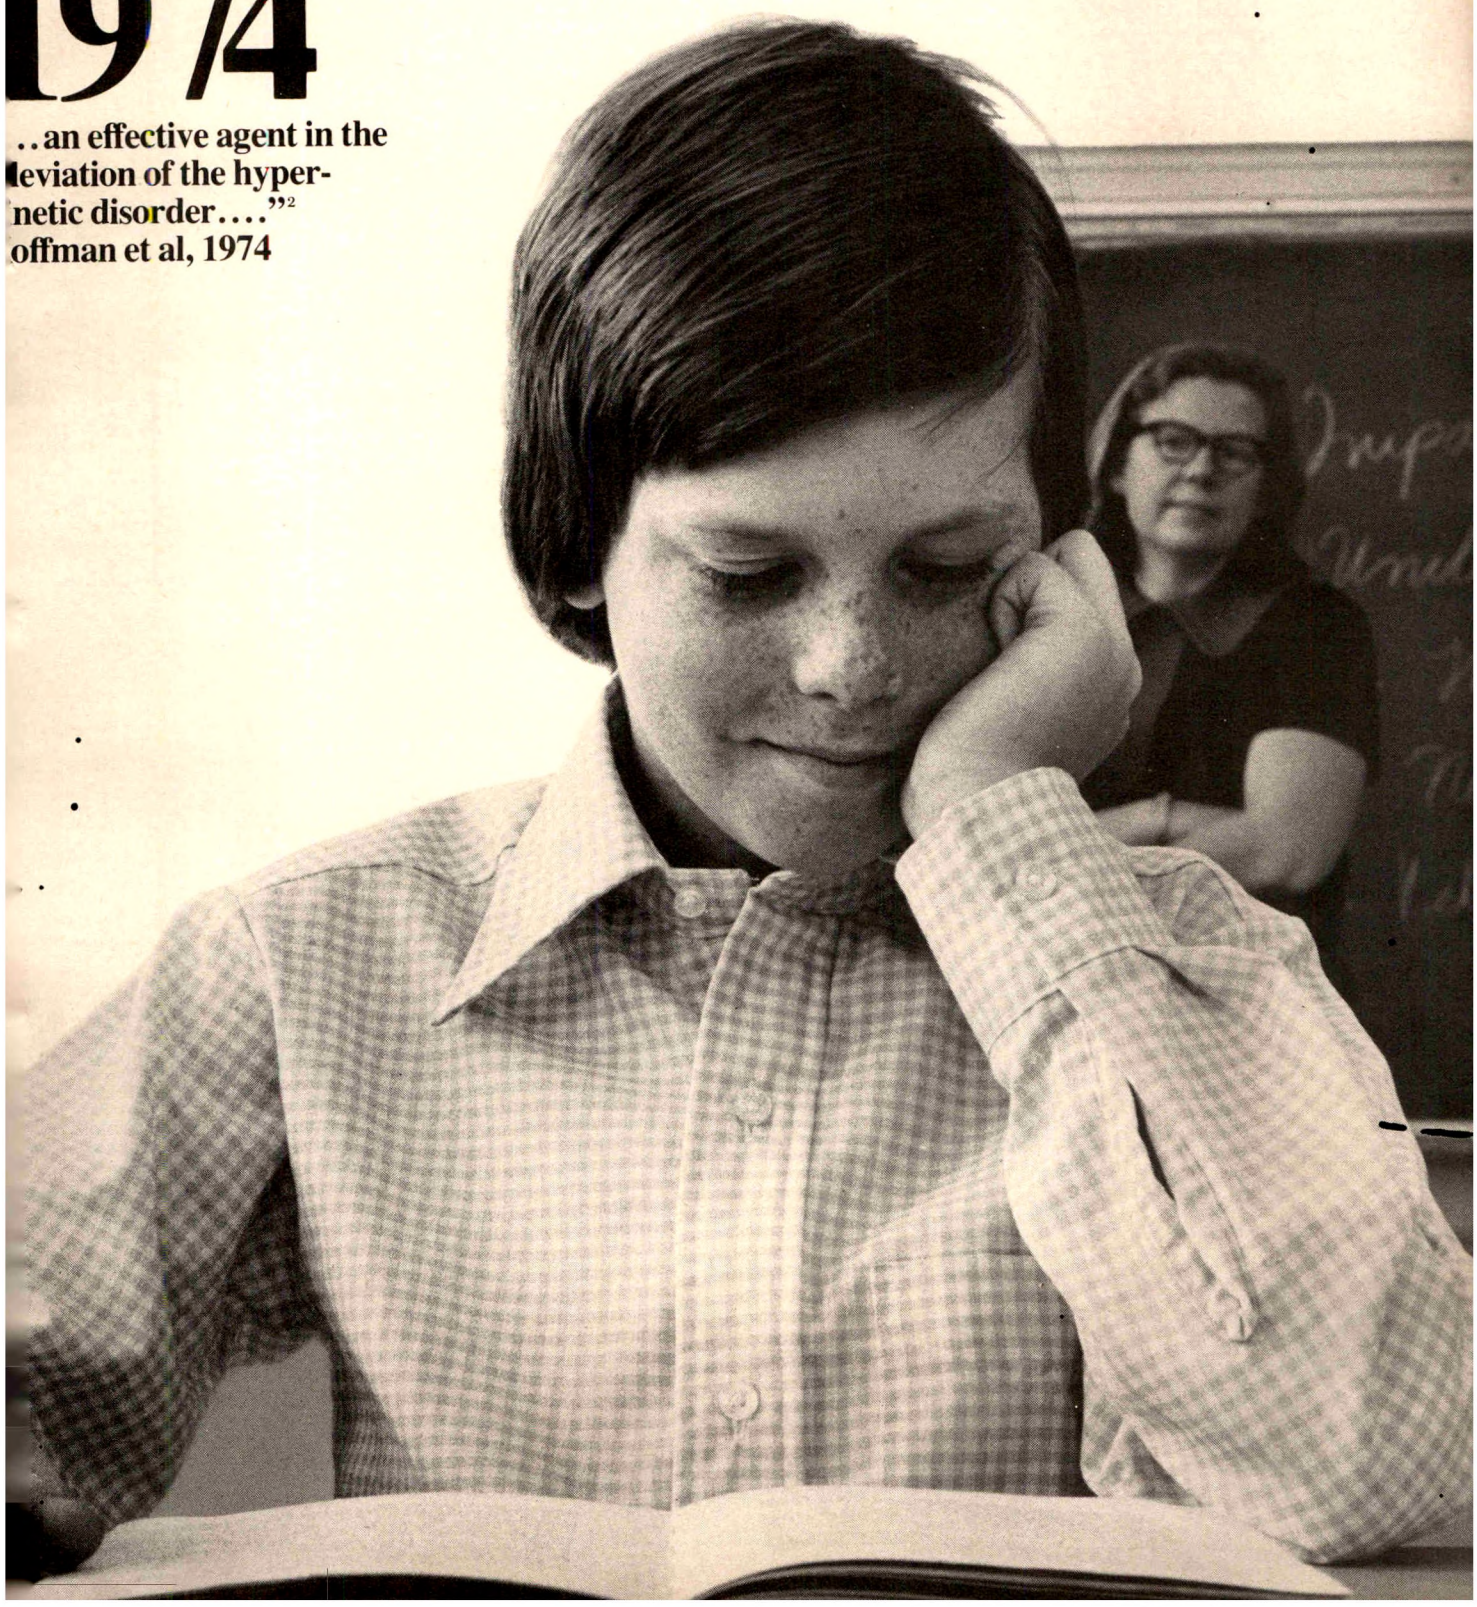
Over a decade of controlled studies and clinical experience has shown the effectiveness of Ritalin in reducing the hyperactivity,[1-3] distractibility,[1,4,5] and disorganized behavior[1-8] in the MBD child.

By lessening the effects of motor and attentional disorders, Ritalin can help the MBD child to better focus his attention on meaningful stimuli and thus can often improve cognition and promote learning.[6,9]

And side effects – insomnia and appetite loss – with Ritalin have occurred less frequently than with dextroamphetamine.[10,11]

Indeed, Ritalin is currently a drug of choice in many MBD situations,[10,12] and can prove to be an important element in many complete remedial programs for MBD.

Therapy with Ritalin should be undertaken only after a medical diagnosis of MBD has been made. Drug treatment is not indicated for all children with MBD.



Dosage should be periodically interrupted. Often, these interruptions reveal some "stabilization" in the child's behavior even without medication, permitting a reduction in dosage and eventual discontinuance of drug therapy.

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak® blister units of 100

Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

Where The Action Is—

For more than a decade the general hospital psychiatric unit has been the principal locus of inpatient treatment. This latest Joint Information Service national survey brings up to date its earlier—and the original—study of this important component of the psychiatric scene. It reveals that the remarkable rate of growth held up, showing an increase of 50 percent in the number of units between 1963 and 1971, and an increase of 46 percent in the number of admissions. And it verifies that general hospital psychiatry has become increasingly comprehensive, with an impressively high level of outpatient service, emergency service, and even consultation to community agencies. Indeed, the general hospital accounts for several times as much service and activity as the widely heralded federally supported community mental health center.

This study also involves the private psychiatric hospitals, which have not changed much in number but are admitting about 10,000 more patients than in 1964—and they, too, are providing a remarkably comprehensive program.

It's your responsibility to be well-informed about these extraordinarily significant and vital pieces of American psychiatric service. You can do so by sending the order form below.

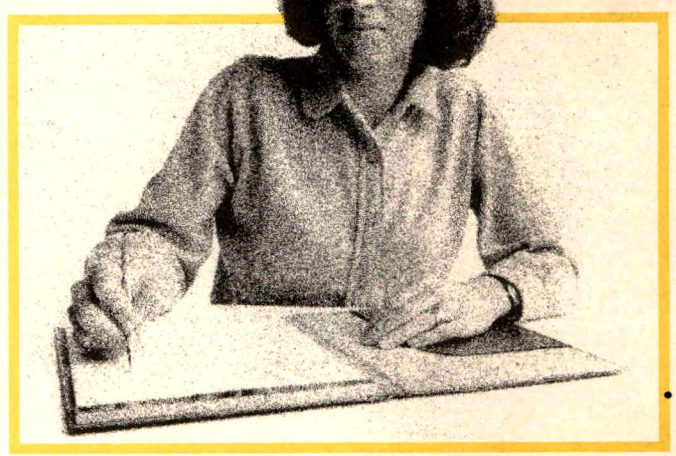
Introducing

The unforgettable antidepressant

Endep™ 75 mg

amitriptyline HCl/Roche

Here's what makes it unforgettable



Patients are more likely to remember the single bedtime dosage of Endep (amitriptyline HCl).

You'll remember 1 or 2 tablets *h.s.*, because fewer forgotten doses produce a more consistent clinical effect, and because it is the only tricyclic antidepressant scored for easy titration.

Patients will also remember family/interpersonal relationships that they have forgotten or neglected.

In three or four weeks patients will usually remember how well they used to feel.

Endep™ 75 mg

amitriptyline HCl/Roche

The antidepressant you can prescribe at night to work all day

Before prescribing, please consult complete product information, a summary of which appears on the following page.

Introducing Endep™

amitriptyline HCl/Roche

The antidepressant you can prescribe at night to work all day

(orange)	(orange)	(orange)	(yellow)
10-mg scored tablets	**25-mg** scored tablets	**50-mg** scored tablets	**75-mg** scored tablets

■ Endep (amitriptyline HCl), in responsive patients, lifts mood and relieves symptoms such as anorexia, loss of interest, inability to concentrate, decreased libido or GI disturbances, often within three or four weeks after starting therapy.

■ Endep usually relieves accompanying sleep disturbances, particularly early in the treatment regimen.

■ All four dosage strengths are scored for greater flexibility and convenience in titration.

■ The 75-mg *h.s.* dose minimizes skipped doses, maximizes patient acceptance and compliance.

■ Specifying Endep/Roche assures quality plus potential economy.

Important Considerations

Should not be given concomitantly with an MAO inhibitor.

Not recommended for use during the acute recovery phase following myocardial infarction.

Contraindicated in patients with hypersensitivity to amitriptyline.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: To relieve symptoms of depression (notably endogenous depression) and depression accompanied by anxiety.

Contraindications: Known hypersensitivity. Do not use with monoamine oxidase (MAO) inhibitors or within at least 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Use not recommended during acute recovery phase after myocardial infarction.

Warnings: May block action of guanethidine or similar antihypertensives. Use with caution in patients with history of seizures, urinary retention, angle closure glaucoma, increased intraocular pressure. Closely supervise cardiovascular patients, hyperthyroid patients and those receiving thyroid medications. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, including amitriptyline HCl, especially in high doses. Myocardial infarction and stroke reported with use of this class of drugs.) May impair alertness; warn against hazardous occupations or driving a motor vehicle during therapy. Weigh potential benefits against hazards during pregnancy, the nursing period and in women of childbearing potential. Not recommended in children under 12.

Precautions: May exaggerate symptoms in schizophrenic and paranoid patients, or shift manic-depressives to manic stage; reduce dose or administer major tranquilizer concomitantly. Close supervision and careful dose adjustments required when given with anticholinergic or sympathomimetic agents. Exercise care in patients receiving large doses of ethchlorvynol; transient delirium reported with concomitant administration. May enhance effects of alcohol, barbiturates and other CNS depressants. Because of the possibility of suicide in depressed patients, do not permit easy access to large drug quantities in these patients. Because it may increase hazards of electroshock therapy, limit concomitant use to essential treatment. If possible, discontinue drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: This list includes a few adverse reactions not reported with this specific drug but requiring consideration because of similarities of tricyclic antidepressants. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, eosinophilia. purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache and malaise. These are not indicative of addiction.

Dosage: Initiate at low levels; increase gradually, watching for signs of intolerance. As long as 30 day may elapse before adequate antidepressant effect develops; sedative effect may be noted earlier. *Initial Adult Dosage:* Outpatients — 25 mg t.i.d.; may be increased to 150 mg/day. Add increased drug to afternoon and/or bedtime doses. Alternate — 50 to 100 mg h.s., gradually increasing h.s. dos up to 150 mg/day. Hospitalized Patients — Up to 100 mg/day; increase gradually to 200 mg if necessary. A few patients may require 300 mg/da *Adolescent and Elderly Patients:* In general, 10 m t.i.d. with 20 mg h.s. may be satisfactory for those who do not tolerate higher doses. *Maintenance Dosage:* With symptomatic improvement, reduce dosage to lowest amount that gives relief, usually 25 mg b.i.d. to q.i.d., or 10 mg q.i.d. Continue maintenance therapy 3 months or longer to avoid relapse.

Overdosage: Immediately hospitalize patient suspected of having taken an overdose. Treatment is symptomatic and supportive. IV administration of 1 to 3 mg physostigmine salicylate reported to reverse the symptoms of amitriptyline poisoning. See complete product information for manifestations and treatment.

Supplied: 10-mg, 25-mg, 50-mg and 75-mg scored tablets — bottles of 100 and 500; Prescription Pak of 60 (10 mg, 25 mg and 50 mg) or 30 (75 mg), available singly and in trays of 10.

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

James N. Sussex, M.D.
President, American Association of Psychiatric Services for Children

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication.

TRIAVIL is contraindicated in CNS depression from drugs; in the presence of evidence of bone marrow depression; and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to other drugs or mask other disorders. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® **containing perphenazine and amitriptyline HCl**

a tranquilizer-antidepressant

for highly effective relief of depression with moderate anxiety

TRIAVIL®

containing perphenazine and amitriptyline HCl a tranquilizer-antidepressant

Available:

TRIAVIL® 2-25: Each tablet contains 2 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 2-10: Each tablet contains 2 mg perphenazine and 10 mg amitriptyline HCl

TRIAVIL® 4-25: Each tablet contains 4 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 4-10: Each tablet contains 4 mg perphenazine and 10 mg amitriptyline HCl

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

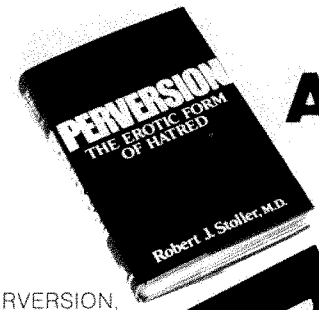
Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.

Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and that the full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.



Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude, muscle weakness, mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

MERCK SHARP & DOHME

A remarkable new study of sexual aberration

PERVERSION

PERVERSION, the fourth work in Dr. Robert Stoller's major series on sex and gender identity, is an in-depth exploration of the psychological forces that contribute to sexual excitement in men and women, and includes fascinating case materials documenting how perversions evolve from early childhood traumas into fantasies and sexual hostility.

"Recommended most heartily. It is an elegant and subtle disquisition upon the essential 'meaning' of the sexual perversions; and its author is that rare bird, a distinguished scientific authority who seems to revel and pleasure in the uses of language. The intelligence and force of Stoller's writing style cannot be conveyed here, nor can the sheer pleasure of his theoretical fireworks." —MAGGIE SCARF, *The New Republic*

"Robert Stoller presents the problem of perversion with his usual honesty and directness. He is able to rescue the concept of perversion from reactionary moralists who condemn it as a sin and from woolly-minded liberals who would dispense with it altogether. He makes it a subject for scientific investigation and human understanding."
—JULIET MITCHELL, author of *Psychoanalysis and Feminism*

THE EROTIC FORM OF HATRED

201 East 50th St., New York 10022

"A gem, a marvelously helpful and readable statement...

on the strengths and weaknesses of the major psychotherapies and the men and women who practice them."
—Dr. Thomas J. Cottle

"The most personal and satisfying book of its kind published this season. What is so very good about Kovel's approach is his grasp of the genuine values (and the dangers) of the variations of each of the three broad schools—psychotherapy, biotherapy, sociotherapy (couch, chemicals and come-together)."
—Publishers Weekly

"The book is much more than just a well-organized guide; it is grounded in a deeply considered definition of neurosis, therapy, and transference in the political and moral context of human nature and modern life. It includes a fascinating genealogy and a flexible classification of therapeutic schools, as well as a valuable anticipation of questions that may nag the potential patient."
—Kirkus Reviews

A COMPLETE GUIDE TO THERAPY

From Psychoanalysis to Behavior Modification

by JOEL KOVEL, M.D.

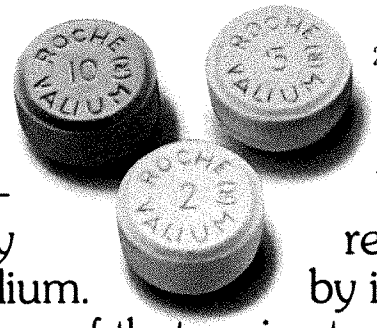
Associate Professor of Psychiatry, Albert Einstein College of Medicine

$10, now at your bookstore

Valium® (diazepam) is a benzodiazepine with a character all its own. Pharmacologically, it has been described as more potent mg-per-mg than other available anxiolytic benzodiazepines. Pharmacokinetically, only Valium provides active *diazepam* as well as the active metabolites 3-hydroxydiazepam, desmethyldiazepam and oxazepam.

But the individual character of Valium is even more apparent clinically. And far more significant. That's because of the patient response obtained with Valium. A response which brings a calmer frame of mind. A response which has a pronounced effect on the somatic symptoms of anxiety, particularly muscular tension. A response which helps the patient feel more like himself again because of the way Valium reduces the overwhelming symptoms of anxiety and psychic tension.

Another important aspect of the clinical character of Valium (diazepam) is safety. Though drowsiness, ataxia and fatigue are possible, these and more serious side effects are rarely a problem. Of course, as with all CNS-acting drugs, patients taking Valium should be cautioned against driving, operating dangerous machinery or consuming alcoholic beverages.



Unquestionably, many psychotherapeutic agents, including other benzodiazepines, have antianxiety effects. But one fact remains: you get a certain kind of patient response with Valium. It's a response you want. A response you know. A response you trust as part of your overall management of anxiety and psychic tension.

A prudent choice in psychic tension and anxiety.

Please turn page for a summary of product information.

ROCHE

Valium® (diazepam) IV has a character all its own.

2-mg, 5-mg, 10-mg scored tablets

Initial calming in hours. Your anxious patient will be reassured by the prompt action of Valium. It's immediate, tangible proof that the medication is working.

Significant improvement in days. Because of the way Valium reduces the overwhelming symptoms of anxiety and psychic tension, your patient begins to feel more like himself again often within a few days.

Patient response you know, want and trust. You get a certain kind of response with Valium. It's a pronounced response. A response which, by its very nature, quickly begins to restore the patient's lost sense of well-being. And, of course, at recommended dosages, Valium offers a wide margin of safety.

Pharmacokinetic predictability. Valium has demonstrated a highly reliable and consistent pattern of absorption, distribution, metabolism and excretion—one more indication of its overall reliability of performance.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders; athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10.

The George Washington University Medical Center is seeking a Chairperson of the Department of Psychiatry and Behavioral Science. The Department has a full time faculty of 10 persons, and a large voluntary faculty throughout the metropolitan Washington area. Resources include a 33 bed unit within the University Hospital, an ambulatory facility caring for 10,000 visits per year, a substantial research program centered on family therapy and drug and alcohol abuse, a training program to include 6 residents per year, and extensive input into each of the 4 years of the medical school curriculum. Capacity to develop liaison with Washington psychiatric community and mental health resources is a Medical Center priority. Applicant should have significant experience in administration in a medical school or related programs. Write Thomas E. Piemme, M.D., Chairman, Search Committee, 1229 25th Street, N.W., Washington, D.C. 20037. An equal opportunity employer.

Psychiatrists

We are a large progressive community based JCAH accredited and medical school affiliated psychiatric facility undergoing accelerated expansion of services. Present openings for INPATIENT AND OUTPATIENT STAFF PSYCHIATRISTS require licensure in any state or in Canada by examination and completion of approved psychiatric residency program. We offer a starting salary commensurate with your background, comprehensive fringe benefits and an innovative environment conducive to ongoing professional development.

Send C.V. in confidence to, or contact,

The vulnerable ages

The first epileptic seizure is most likely to occur during early childhood and at the onset of puberty

About 9 out of 10 epileptics experience their first seizure before the age of 20—with the highest incidence between 5 and 7, when children start school, and at the onset of puberty, a time of physiological and psychic turmoil.[1] The most common type, grand mal, occurs in approximately 75% of epileptic children,[1] and more than 50% of patients who suffer initially from petit mal develop grand mal seizures before they reach the age of 16.[2]

Mysoline (primidone) for control of grand mal, psychomotor and focal epilepsy

At the onset and afterwards — used alone or as concomitant therapy, MYSOLINE may reduce the frequency and severity of major motor seizures—or even eliminate them. *Excellent* for control of grand mal. Valuable for control of psychomotor[1,3,4] and focal epilepsy as well.[5]

Add Mysoline when control with other anticonvulsants is inadequate—As concomitant therapy, MYSOLINE can improve seizure control in grand mal and psychomotor epilepsy. The combined use of phenobarbital, diphenylhydantoin, and MYSOLINE may have additive anticonvulsant effects without additive side effects.[6]

Change to Mysoline when other anticonvulsants fail—A changeover to MYSOLINE is frequently warranted when other anticonvulsants must be discontinued because of important side effects, or when grand mal seizures are refractory to phenobarbital, with or without diphenylhydantoin.[7]

Mysoline® (primidone)

may be the start of a better life for the epileptic

initial and maintenance therapy for
grand mal, psychomotor and focal epilepsy

BRIEF SUMMARY
(For full prescribing information, see package circular.)

MYSOLINE® Brand of PRIMIDONE
Anticonvulsant

ACTIONS: MYSOLINE acts on the central nervous system to raise seizure threshold or alter seizure pattern. The mechanism(s) of action of anticonvulsant drugs is not known.

Primidone has anticonvulsant activity *per se*. In addition, its two metabolites possess anticonvulsant qualities. The major metabolite is phenylethylmalonamide (PEMA); the other is phenobarbital. In addition to its own anticonvulsant potential, PEMA potentiates phenobarbital.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several days before it can be assessed.

Use in pregnancy: Recent reports strongly suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Reference has been made to primidone in several cases in which it was used *in combination* with other anticonvulsants; but its teratogenicity has not been conclusively demonstrated. The possibility exists that other factors, *e.g.*, genetic factors or the epileptic condition, may contribute to the higher incidence of birth defects. The data also indicate that the great majority of mothers receiving anticonvulsant medication deliver normal infants.

Anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and risk to both mother and the unborn child.

When the nature, frequency, and severity of the seizures do not pose a clear threat to the patient, good medical practice requires that the physician weigh the expected therapeutic benefit of anticonvulsant therapy against possible risk on an individual basis.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

The physician should weigh all of the foregoing considerations when treating and counseling epileptic women of childbearing potential.

PRECAUTIONS: The total daily dosage should not exceed 2 Gm. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

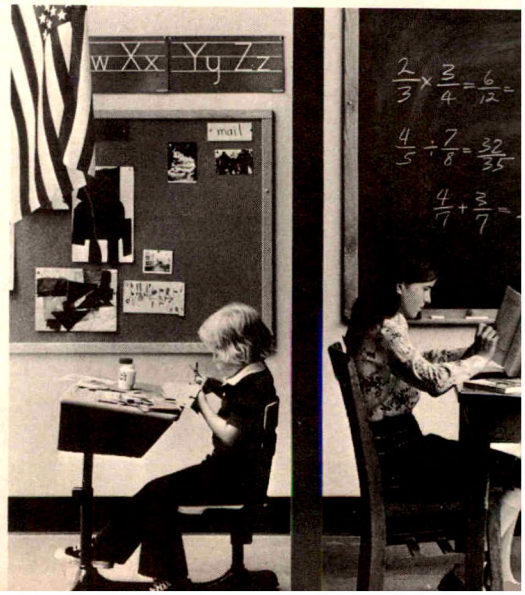
ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid, 15 mg. daily, without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 Gm. per day. The initial dose is 250 mg. Increments of 250 mg. are added, usually at weekly intervals, to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 Gm. A typical dosage schedule for the introduction of MYSOLINE (primidone) is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg. daily at bedtime	*2nd Week* 250 mg. b.i.d.
3rd Week 250 mg. t.i.d.	*4th Week* 250 mg. q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg., with gradual weekly increases of 125 mg. a day, to a daily total usually between 500 mg. and 750 mg.



In patients already receiving other anticonvulsants: MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg. Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances:

- for initiation of combination therapy
- during "transfer" therapy
- for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.)

HOW SUPPLIED: MYSOLINE *Tablets*—No. 430—Each tablet contains 250 mg. of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431—Each tablet contains 50 mg. of primidone (scored), in bottles of 100 and 500. MYSOLINE *Suspension*—No. 3850—Each 5 cc. (teaspoonful) contains 250 mg. of primidone, in bottles of 8 fluid-ounces.

Basic tools of primitive psychiatry

Mankpo: Sceptres or staffs used by the Heviosso (lightning God) cult in medical ceremonies among the Ewe of Tongo and Fon of Dahomey. *Right,* staff with leopard's head, bared teeth and tongue (Ewe, Togo). *Left,* staff with ram's head—the sacred animal of the Heviosso—in the form of a serpent symbolizing the fire-spitting rainbow God of healing (Fon, Dahomey). From the collection of the Segy Gallery, New York City.

Basic tool of Western psychiatry

Thorazine®
(chlorpromazine, SK&F)

Tablets: 25 and 50 mg of the HCl

- 'Thorazine' controls psychotic symptoms
- Especially useful in agitated, violent or anxious schizophrenic patients
- Unsurpassed clinical experience
- 18 convenient dosage forms and strengths

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudo-parkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only). Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only). Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

For effective management of schizophrenic symptoms.

The familiar refrain of depression: morning fatigue... sadness... anorexia... insomnia

Now, Merrell offers Norpramin (desipramine hydrochloride tablets N.F.) to effectively relieve these common manifestations of depression.

Norpramin also provides additional benefits in treatment of your patients.

- ☐ effectively relieves physical, psychological and emotional symptoms of depression
- ☐ minimal daytime sedation — important for patients who must be alert to perform daytime activities
- ☐ relief that may begin in 2 to 5 days — but full therapeutic effect is seldom seen before 2 weeks
- ☐ side effects rarely require discontinuation of therapy
- ☐ increases interpersonal responsiveness
- ☐ can help facilitate psychotherapy

Prescribe Norpramin to change the familiar refrain of depression in your practice.

Norpramin®
(desipramine hydrochloride tablets N.F.)

Brief Summary

Indications: Norpramin (desipramine hydrochloride tablets N.F.) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.

Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease. (b) with a history of urinary retention or glaucoma. (c) with thyroid disease or those on thyroid medication. (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.

Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. If possible, dispense in child-resistant containers. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosis in schizophrenic patients. Use cautiously with anticholinergic or sympathomimetic drugs. Response to alcoholic beverages may be exaggerated. In the concurrent administration of ECT and antidepressant drugs one should consider the possibility of increased risk relative to benefits. Discontinue as soon as possible prior to elective surgery because of possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients on desipramine hydrochloride. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy: the drug should be discontinued if there is neutropenia.

Adverse Reactions: *Cardiovascular:* hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke. *Psychiatric:* confusional states (especially in the elderly), hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever, cross sensitivity with other tricyclic drugs. *Hematologic:* bone marrow depressions including agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss, perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily; increase to 100 mg. daily if necessary.

Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.

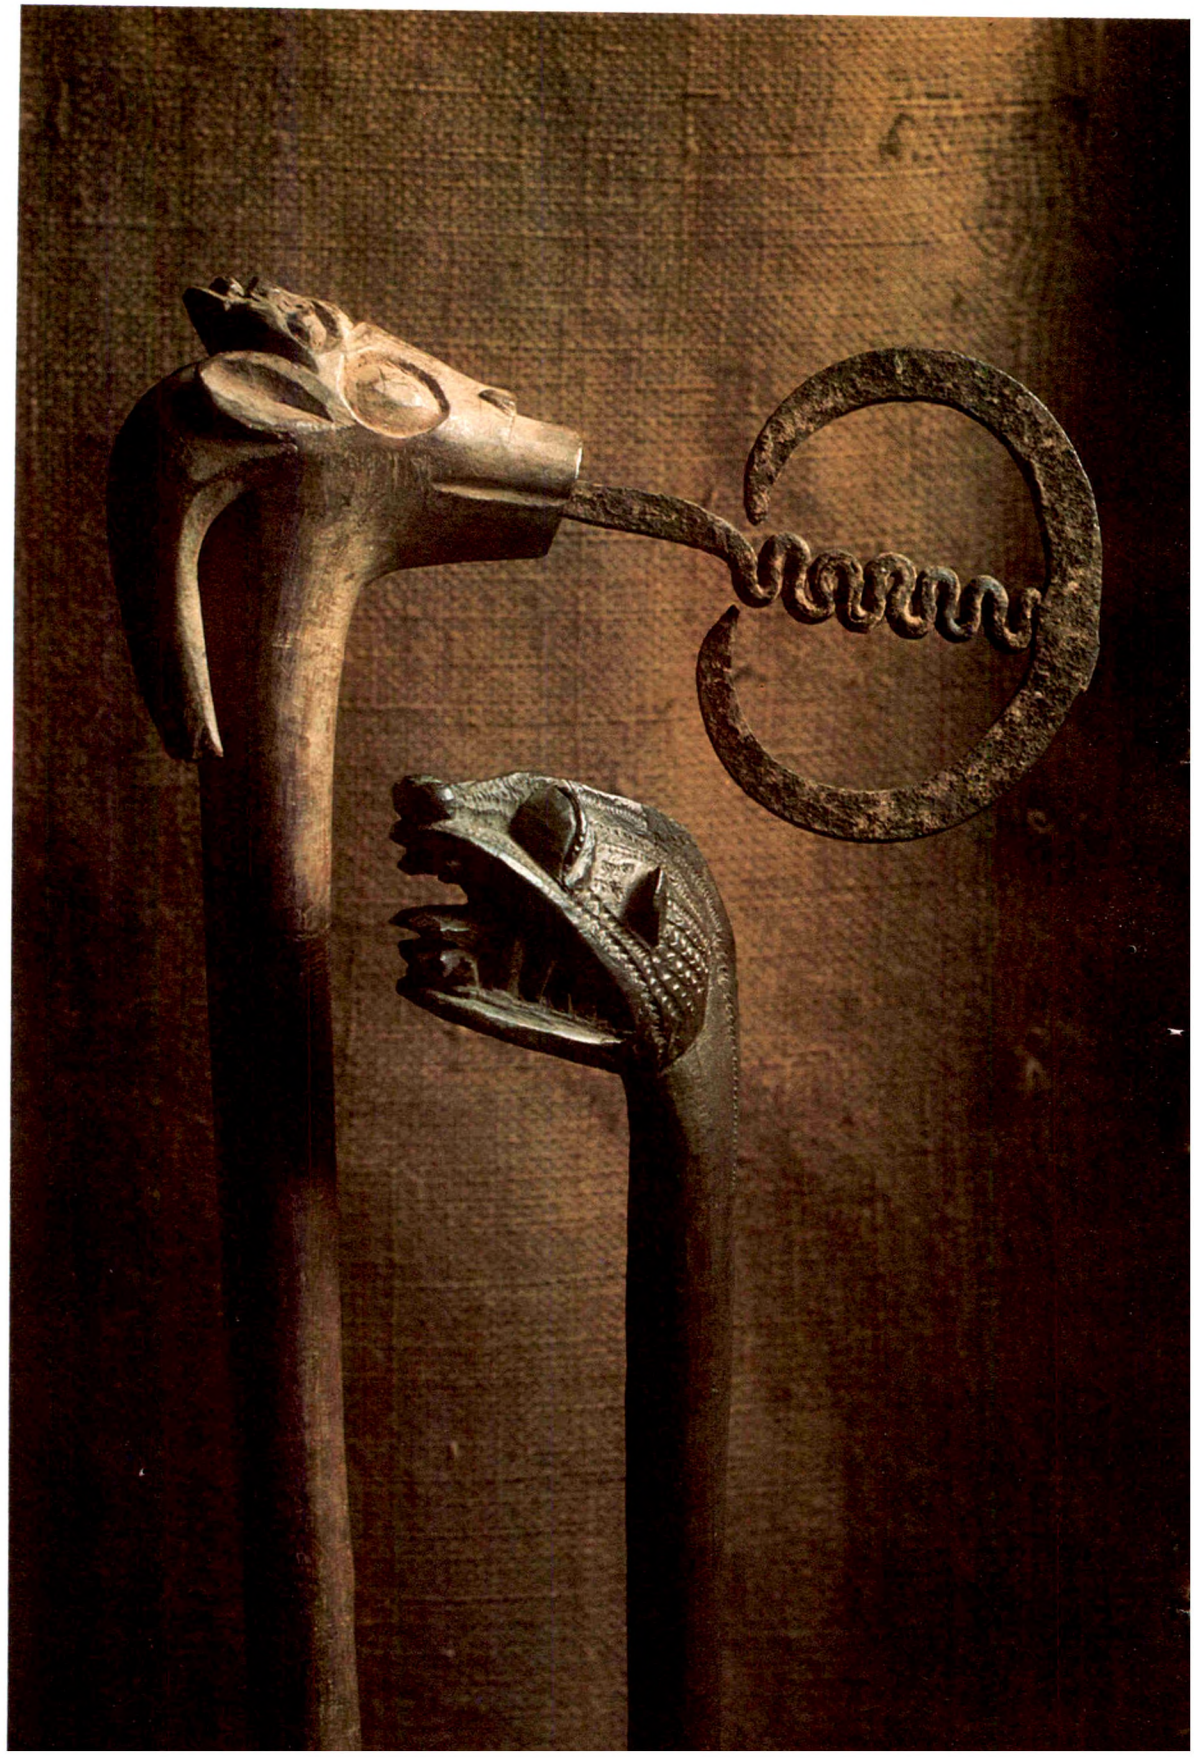
THE AMERICAN JOURNAL OF PSYCHIATRY



In this issue

Overview: Psychiatric Sequelae to Multiple Trauma by Nathan Schnaper and R Adams Cowley

OFFICIAL JOURNAL OF THE
AMERICAN PSYCHIATRIC ASSOCIATION

Basic tools of primitive psychiatry

Mankpo: Sceptres or staffs used by the Heviosso (lightning God) cult in medical ceremonies among the Ewe of Tongo and Fon of Dahomey. *Right,* staff with leopard's head, bared teeth and tongue (Ewe, Togo). *Left,* staff with ram's head—the sacred animal of the Heviosso—in the form of a serpent symbolizing the fire-spitting rainbow God of healing (Fon, Dahomey). From the collection of the Segy Gallery, New York City.

Basic tool of Western psychiatry

Thorazine®
(chlorpromazine, SK&F)

Tablets: 25 and 50 mg of the HCl

- 'Thorazine' controls psychotic symptoms
- Especially useful in agitated, violent or anxious schizophrenic patients
- Unsurpassed clinical experience
- 18 convenient dosage forms and strengths

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudo-parkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only). Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only). Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

Coverage and Utilization of Care for Mental Conditions Under Health Insurance —Various Studies, 1973–74

By Louis S. Reed, Ph.D.
Consultant in Health Economics, American Psychiatric Association

This book reports six studies that add to the growing body of data demonstrating the feasibility of covering mental illness under health insurance. Although in some ways it may be considered a supplement to APA's 1972 book **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (Reed, Myers, and Scheidemandel), all of the data are new. The studies cover the following areas:

- Utilization of mental benefits under the Blue Cross and Blue Shield plan for federal employees, documenting that a "plateau" in the use of these benefits was reached in 1973–74.
- Comparison of benefits for mental and other illnesses under selected employee health benefit plans.
- Coverage of mental illness under collective bargaining agreements of selected unions.
- Utilization of care for mental conditions under the Canadian health insurance program, which gives the same coverage for mental as for other conditions.
- Updating of information on Blue Cross benefits for hospital care of mental illness.
- Data from selected Blue Cross and Blue Shield plans on coverage and utilization of mental conditions, with emphasis on major medical coverage.

80pp. Paperbound

Single copy, $4.00; 10–49 copies; $3.80 each; 50 or more copies, $3.20 each.

SPECIAL OFFER: One copy of this book (regular price, $4.00) and one copy of **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (regular price, $6.50) for $8.50.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone, should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; with other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there will usually be a charge for granting this permission.

Informed consent. Manuscripts that report the results of experimental investigation on human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure had been fully explained.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

All measurements must be in metric units.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal's* Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed 8 typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the coauthor who has been designated to assume responsibility for the paper and reprint requests. The number of authors should be limited to principal researchers and writers, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the syle used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Tables and figures should be self-explanatory and should supplement, not duplicate, the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the paper. Most figures will be reduced to about 3¼ inches in width; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHORS' CORRECTIONS

After the paper has been scheduled for publication, the edited manuscript will be sent to the first-named author for corrections and answers to queries. Prompt return is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after being notified of the acceptance of his paper, he should inform the *Journal* office or arrange with a coauthor to assume responsibility for the paper. Galley proofs will not be sent to authors.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

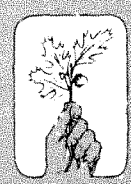
Three Treatment Centers

Three treatment centers provide individually prescribed programs of care, education, treatment and training for children, adolescents and adults with learning disabilities, neurological impairment, mental retardation or emotional disturbance.

Advantage: the availability of a **large, trained and experienced staff,** exchanging ideas and insights in a comprehensive program of supportive environment and individualized treatment.

Advantage: **geographically separated** to provide the proper residential milieu . . . yet near enough to benefit from the combined training and experience of a wide range of staff members.

The Oaks — A residential psychiatric treatment center for emotionally disturbed children and adolescents between the ages of six and 18. Coeducational, Austin. In addition, the Center provides a Short Term Adolescent Center and a six bed intensive care unit.



The San Marcos Treatment Center — a facility with three campuses designed for individuals with psychiatric, neurological, and intellectual difficulties who have evidenced a need for a 24-hour therapeutic milieu.

The Center offers a broad spectrum of services to both mentally retarded individuals and those with psychiatric disorders. In addition to a structured therapeutic environment, individual and group psychotherapy services are available to each resident. Clinical supervision and support services are provided by the Center psychiatrists.

The Ranch Treatment Center — located in the suburbs of Austin the Center provides both long-term and intermediate tenure services to multi-handicapped male adolescents and adults whose primary diagnostic classifications are in areas of mental retardation and mental illness. All residents receive program services which may permit their early discharge to the less restrictive settings of community-based programs.

The American Journal of Psychiatry

will feature

- Overview: Research on the Psychology of Women. I. Sexual and Reproductive Life by Anne M. Seiden

Put depression to rest

The h.s. schedule: provides symptomatic relief throughout the next day.

Because of its pharmacokinetic characteristics, Endep (amitriptyline HCl) Roche, provides the same clinical effect over a period of time when given as a single daily *h.s.* dose or as 1/3 the same dose given *t.i.d.*

The h.s. schedule: helps put side effects in their place.

100 mg Endep *h.s.* can provide relief of depression-induced insomnia. Once asleep, the patients are also less likely to notice anticholinergic side effects—such as dry mouth—which reach a peak hours after the *h.s.* dose.

Midnight

Because the sedative effect may impair patients' performance during daytime, warn patients not to drive or operate dangerous machinery until the sedative potential has been clearly established.

The h.s. schedule: helps maximize patient compliance.

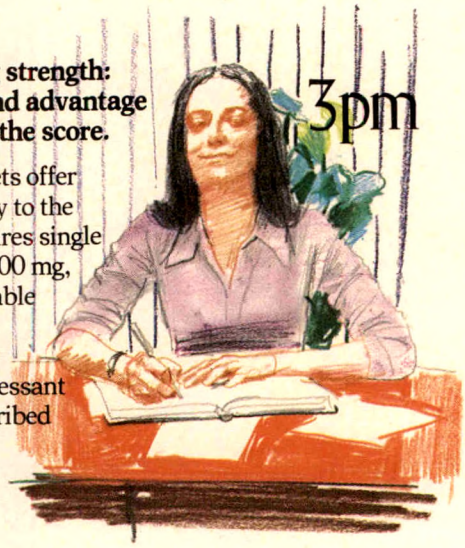
According to one investigation, only 40% of patients comply with a *t.i.d* drug schedule whereas 93% of patients comply with a one-dose-a-day schedule.[1] An *h.s.* schedule of Endep (amitriptyline HCl), therefore, should help you maximize patient compliance which, in turn, helps ensure prompt recovery.

ROCHE

all day long

The 100-mg strength: early signs of progress.

Many depressed patients with insomnia and anorexia begin to show improvement during the first week of Endep (amitriptyline HCl) therapy. Patients with symptoms of "neurotic" depression usually improve during the first week, whereas those with "psychotic" depression usually do not improve until the third week of therapy. However, adequate response may require up to 30 days in both types.



8am

Noon

The 100-mg strength: the economy and advantage of knowing the score.

100-mg tablets offer potential economy to the patient who requires single doses of 50 mg, 100 mg, or 150 mg. Available as scored tablets, Endep is the only tricyclic antidepressant that can be prescribed in half doses.

3pm

The 100-mg strength: emphasis on individualization of dosage.

The introduction of the 100-mg scored tablet brings to 5 the number of Endep dosage strengths now available as scored tablets: 10 mg, 25 mg, 50 mg, 75 mg, and 100 mg.

7pm

with new 100mg Endep®

amitriptyline HCl/Roche

Before prescribing, please consult complete product information, a summary of which appears on the following page.

Endep®

amitriptyline HCl/Roche

10 mg 25 mg 50 mg 75 mg Just released 100 mg

The only tricyclic antidepressant with scored tablets

- By relieving underlying depression Endep (amitriptyline HCl), in responsive patients, lifts mood and relieves symptoms such as anorexia, loss of interest, inability to concentrate, decreased libido or GI disturbances, often within three or four weeks after starting therapy.
- Endep usually relieves accompanying sleep disturbances, particularly early in the treatment regimen.
- All five dosage strengths are scored for greater flexibility and convenience in titration.
- The *h.s.* dosage minimizes skipped doses, maximizes patient acceptance and compliance.
- Specifying Endep assures quality plus potential economy.

Important Considerations

Should not be given concomitantly with an MAO inhibitor or within 2 weeks of its administration.

Patients should use caution in the performance of hazardous tasks such as operating machinery or driving a motor vehicle.

May enhance the effects of alcohol, barbiturates and other CNS depressants.

Not recommended for use during the acute recovery phase following myocardial infarction.

Patients with suicidal tendencies should not have easy access to large quantities of the drug.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: To relieve symptoms of depression (notably endogenous depressions) and depression accompanied by anxiety.

Contraindications: Known hypersensitivity. Do not use with monoamine oxidase (MAO) inhibitors or within at least 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Use not recommended during acute recovery phase after myocardial infarction.

Warnings: May block action of guanethidine or similar antihypertensives. Use with caution in patients with history of seizures, urinary retention, angle closure glaucoma, increased intraocular pressure. Closely supervise cardiovascular patients, hyperthyroid patients and those receiving thyroid medications. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, including amitriptyline HCl, especially in high doses. Myocardial infarction and stroke reported with use of this class of drugs.) May impair alertness; warn against hazardous occupations or driving a motor vehicle during therapy. Weigh possible benefits against hazards during pregnancy, the nursing period and in women of childbearing potential. Not recommended in children under 12.

Precautions: May exaggerate symptoms in schizophrenic and paranoid patients, or shift manic-depressives to manic stage; reduce dose or administer major tranquilizer concomitantly. Close supervision and careful dose adjustments required when given with anticholinergic or sympathomimetic agents. Exercise care in patients receiving large doses of ethchlorvynol; transient delirium reported with concomitant administration. May enhance effects of alcohol, barbiturates and other CNS depressants. Because of the possibility of suicide in depressed patients, do not permit easy access to large drug quantities in these patients. Because it may increase hazards of electroshock therapy, limit concomitant use to essential treatment. If possible, discontinue drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: This list includes a few adverse reactions not reported with this specific drug but requiring consideration because of similarities of tricyclic antidepressants. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache and malaise. These are not indicative of addiction.

Dosage: Initiate at low levels; increase gradually, watching for signs of intolerance. As long as 30 days may elapse before adequate antidepressant effect develops; sedative effect may be noted earlier.

Initial Adult Dosage: Outpatients—25 mg *t.i.d.*; may be increased to 150 mg/day. Add increased drug to afternoon and/or bedtime doses. Alternate—50 to 100 mg *h.s.*, gradually increasing *h.s.* dose up to 150 mg/day. Hospitalized Patients—Up to 100 mg/day; increase gradually to 200 mg if necessary. A few patients may require 300 mg/day.

Adolescent and Elderly Patients: In general, 10 mg *t.i.d.* with 20 mg *h.s.* may be satisfactory for those who do not tolerate higher doses.

Maintenance Dosage: With symptomatic improvement, reduce dosage to lowest amount that gives relief, usually 25 mg *b.i.d.* to *q.i.d.*, or 10 mg *q.i.d.* Continue maintenance therapy 3 months or longer to avoid relapse.

Overdosage: Immediately hospitalize patient suspected of having taken an overdose. Treatment is symptomatic and supportive. IV administration of 1 to 3 mg physostigmine salicylate reported to reverse the symptoms of amitriptyline poisoning. See complete product information for manifestations and treatment.

Supplied: 10-mg, 25-mg, 50-mg, 75-mg and 100-mg scored tablets—bottles of 100 and 500; Tel-E-Dose® packages of 100; Prescription Paks of 60 (10 mg, 25 mg and 50 mg) or 30 (75 mg and 100 mg), available singly and in trays of 10.

SPECIAL BICENTENNIAL ISSUE

July 1976

A Journal of the American Psychiatric Association

Hospital & Community Psychiatry

Two Hundred Years of Mental Health Care in America

Celebrate the Bicentennial with *Hospital & Community Psychiatry*'s July issue, a richly illustrated review of some of the interesting and important developments in mental health care in America over 200 years—from the time of Benjamin Rush to the construction of the first community mental health centers. It's a brief, lively, readable history that you'll want to keep for years. Limited copies are available; order yours today!

[ ] Please reserve _____ copies of *H&CP*'s Bicentennial issue at $2 a copy. My check for $ _____ is enclosed.

[ ] Enclosed is my check for a one-year subscription (12 issues) to *Hospital & Community Psychiatry*. ($12 a year for members of the American Psychiatric and American Psychological Associations; $15 for other subscribers. For subscriptions mailed outside the U.S. add $3 a year. Make checks payable to the American Psychiatric Association.)

Everybody knows somebody who's been helped.

The United Way is reaching out. It goes into every neighborhood. To every age group. Across every income level.
To help. In a thousand ways.
A neighbor. A relative. Maybe someone down the street who's out of work. Or sick. Or in trouble.
Chances are the United Way helps someone you know.
Maybe someday it'll be helping you.

Thanks to you it works...

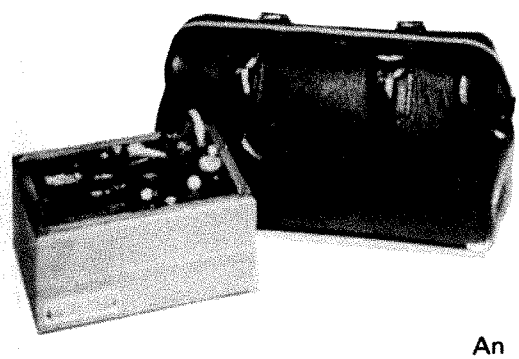
MORE THAN 30 YEARS...

. have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



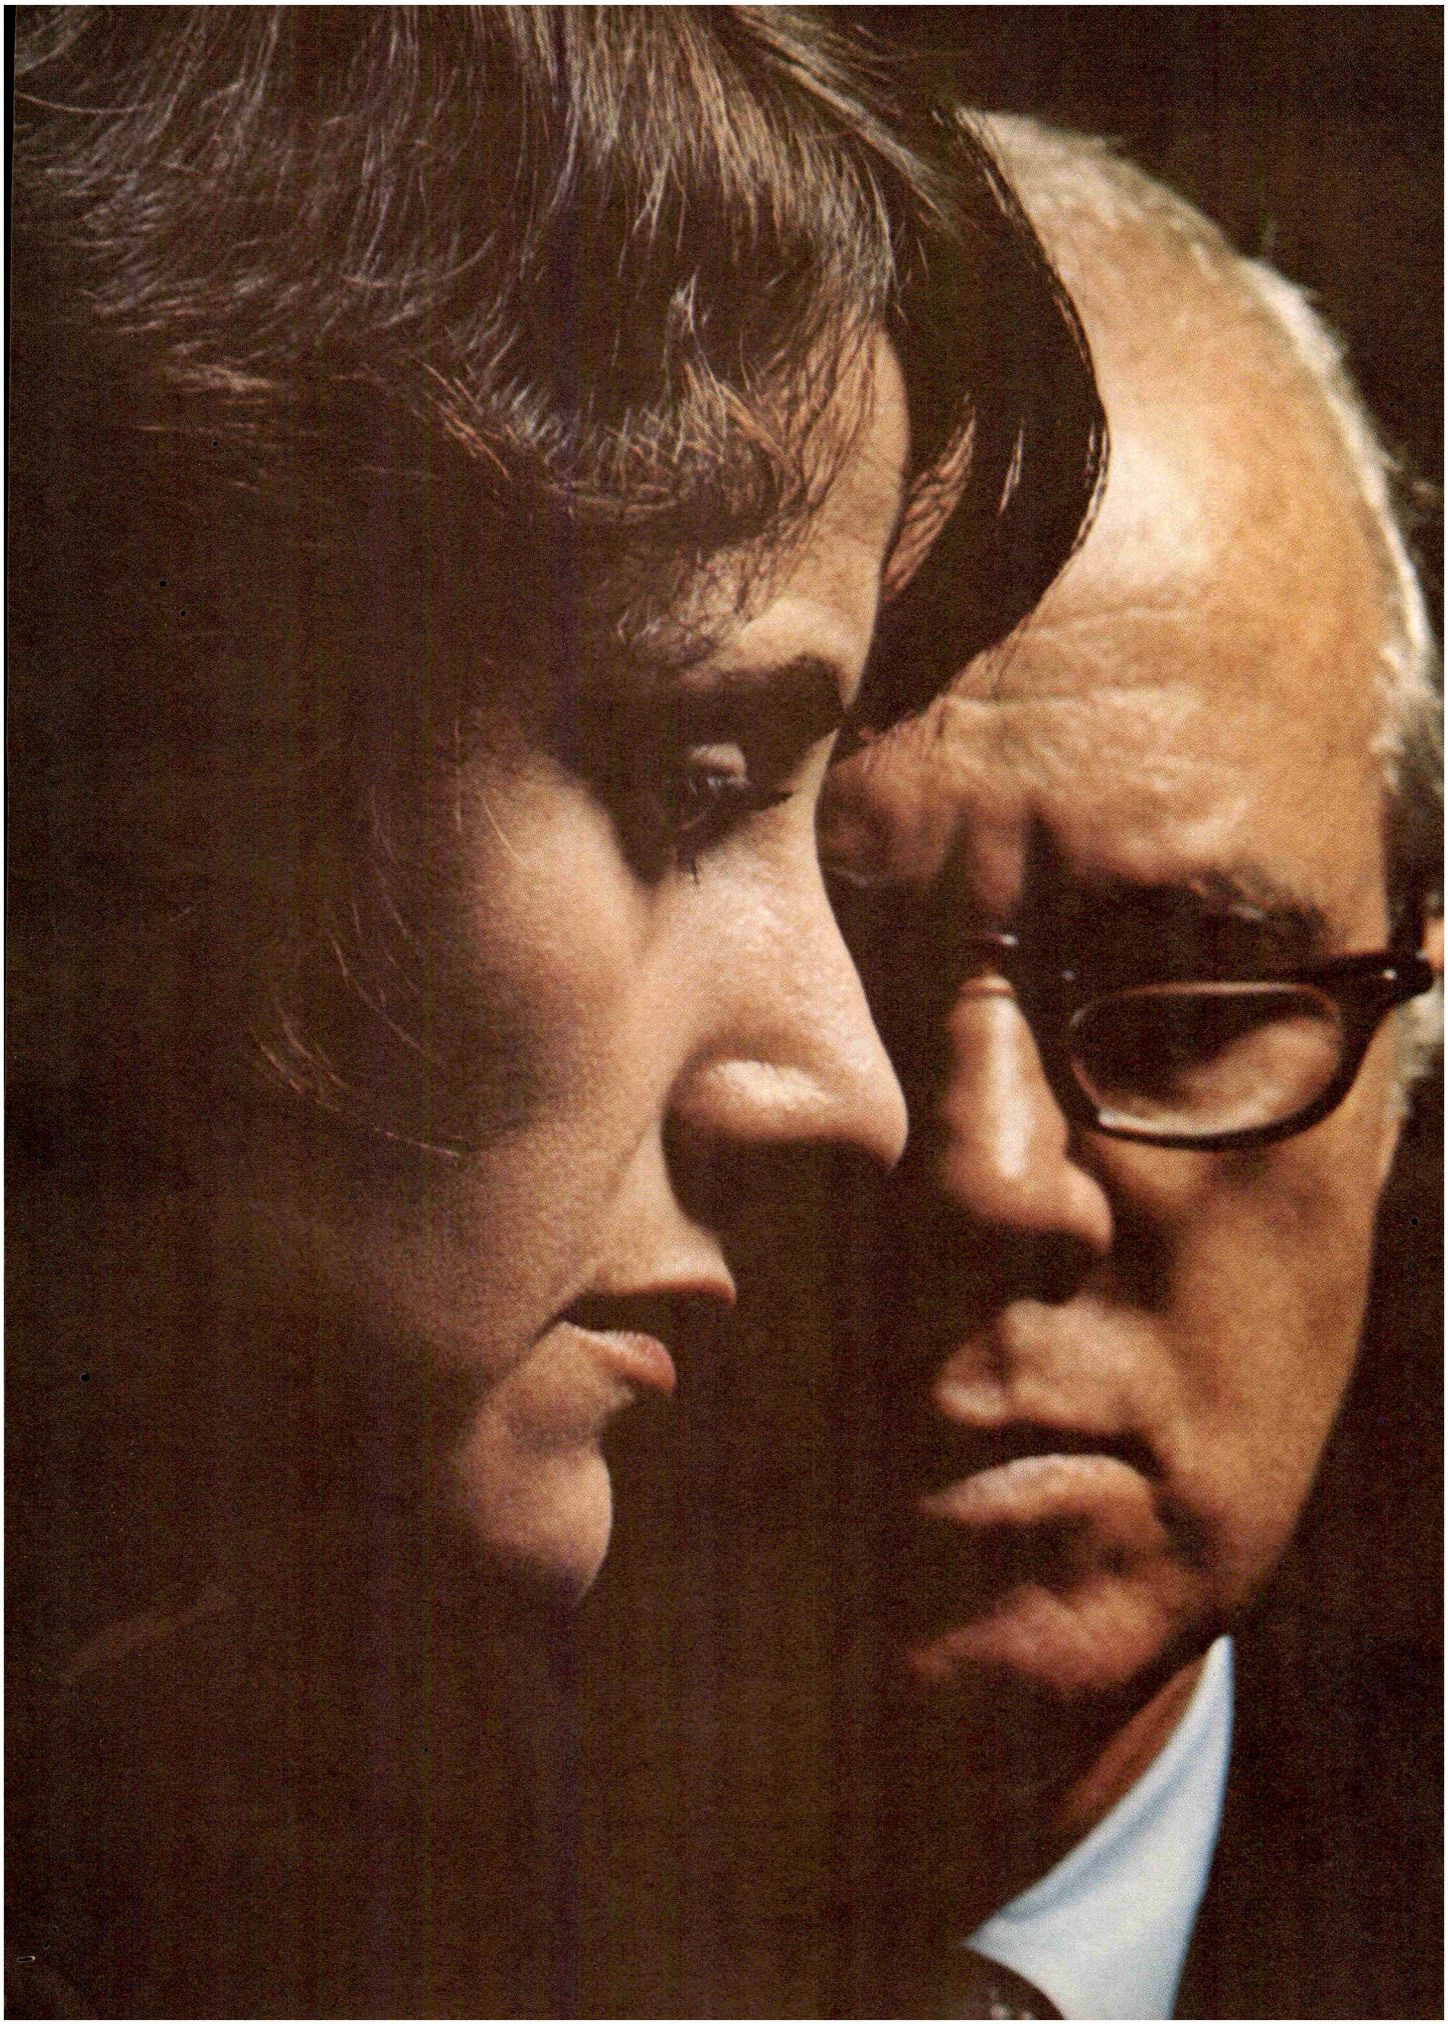
The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.



The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication.

TRIAVIL is contraindicated in CNS depression from drugs; in the presence of evidence of bone marrow depression; and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to other drugs or mask other disorders. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

MERCK SHARP & DOHME

For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® **containing perphenazine and amitriptyline HCl**

a tranquilizer-antidepressant

for highly effective relief of depression with moderate anxiety

TRIAVIL®

containing perphenazine and amitriptyline HCl a tranquilizer-antidepressant

Available:

TRIAVIL® 2-25: Each tablet contains 2 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 2-10: Each tablet contains 2 mg perphenazine and 10 mg amitriptyline HCl

TRIAVIL® 4-25: Each tablet contains 4 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 4-10: Each tablet contains 4 mg perphenazine and 10 mg amitriptyline HCl

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.

Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and that the full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude, muscle weakness, mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia), liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension, hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors, seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

N.Y. ACAD. OF MEDICINE LIBRARY

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

James N. Sussex, M.D.
President, American Association of Psychiatric Services for Children

NEW ORAL CONCENTRATE

Loxitane® C

LOXAPINE HYDROCHLORIDE

Lederle

25 mg base/ml* In bottles of 4 fl. oz.

Effectiveness – the only clue that it's there

DESCRIPTION

*Each ml contains the equivalent of 25 mg loxapine base as the HCl.

LOXITANE *loxapine*, a dibenzoxazepine compound represents a new subclass of tricyclic antipsychotic agent, chemically distinct from the thioxanthenes, butyrophenones, and phenothiazines. Chemically, it is 2-chloro-11-(4-methyl-1-piperazinyl)dibenz[b,f][1,4]oxazepine. It is present in the oral concentrate primarily as the HCl.

ACTIONS

Pharmacologically, loxapine is a tranquilizer for which the exact mode of action has not been established. However, changes in the level of excitability of subcortical inhibitory areas have been observed in several animal species in association with such manifestations of tranquilization as calming effects and suppression of aggressive behavior.

In normal human volunteers, signs of sedation were seen within 20 to 30 minutes after administration, were most pronounced within 1 1/2 to 3 hours, and lasted through 12 hours. Similar timing of primary pharmacologic effects was seen in animals.

Absorption of loxapine following oral or parenteral administration is virtually complete. The drug is removed rapidly from the plasma and distributed in tissues. Animal studies suggest an initial preferential distribution in lungs, brain, spleen, heart, and kidney. Loxapine is metabolized extensively and is excreted mainly in the first 24 hours. Metabolites are excreted in the urine in the form of conjugates and in the feces unconjugated.

INDICATIONS

LOXITANE C *loxapine hydrochloride* is indicated for the manifestations of schizophrenia.

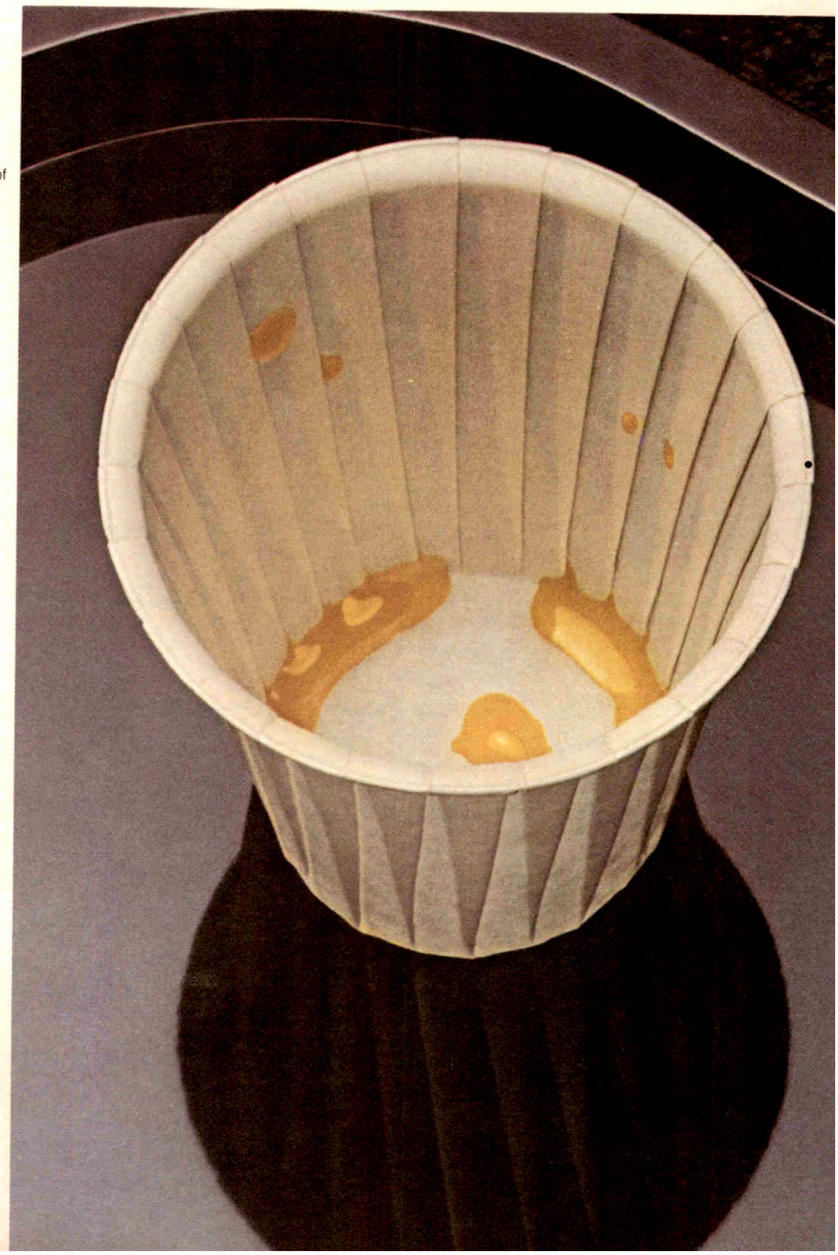
LOXITANE has not been shown effective in the management of behavioral complications in patients with mental retardation.

CONTRAINDICATIONS

LOXITANE is contraindicated in comatose or severe drug-induced depressed states (alcohol, barbiturates, narcotics, etc.)

LOXITANE is contraindicated in individuals with known hypersensitivity to the drug.

WARNINGS



Usage in Pregnancy: Safe use of LOXITANE C *loxapine hydrochloride* during pregnancy or lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the benefits of treatment be weighed against the possible risks to mother and child. No embryotoxicity or teratology was observed in studies in rats, rabbits or dogs, although with the exception of one rabbit study, the highest dosage was only two times the maximum recommended human dose and in some studies they were below this dose. Perinatal studies have shown renal papillary abnormalities in offspring of rats treated from mid-pregnancy with doses of 0.6 and 1.8 mg/kg, doses which approximate the usual human dose but which are considerably below the maximum recommended human dose.

Usage in Children: Studies have not been performed in children; therefore this drug is not recommended for use in children below the age of 16.

LOXITANE C *loxapine hydrochloride*, like other tranquilizers, may impair mental and/or physical abilities, especially during the first few days of therapy. Therefore, ambulatory patients should be warned about activities requiring alertness (e g, operating vehicles or machinery), and about concomitant use of alcohol and other CNS depressants.

PRECAUTIONS

LOXITANE should be used with extreme caution in patients with a history of convulsive disorders since it lowers the convulsive threshold. Seizures have been reported in epileptic patients receiving LOXITANE at antipsychotic dose levels, and may occur even with maintenance of routine anticonvulsant drug therapy.

Tasteless in orange, grapefruit and pineapple juices

Highly acceptable to patients who prefer medication in fruit juices, and a logical alternative to tablets or capsules when good patient management depends on uninterrupted treatment. LOXITANE C Oral Concentrate is as easy to take as the fruit juice in which it may be administered.

Same efficacy as LOXITANE Capsules

Efficacy that speaks for itself with substantial reduction in the symptoms of schizophrenia.

Same favorable side effects profile as with LOXITANE Capsules[1]

In 31 studies involving 469 schizophrenic patients, certain favorable trends were exhibited in the LOXITANE side effects profile; these require further tests and broader clinical experience for confirmation.[1]

Same daily dosage schedule as with LOXITANE Capsules

The dropper is calibrated to conform to usual dosage requirements.

Loxapine has an antiemetic effect in animals. Since this effect may also occur in man, loxapine may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

LOXITANE should be used with caution in patients with cardiovascular disease. Increased pulse rates have been reported in the majority of patients receiving antipsychotic doses; transient hypotension has been reported. In the presence of severe hypotension requiring vasopressor therapy, the preferred drugs may be norepinephrine or angiotensin. Usual doses of epinephrine may be ineffective because of inhibition of its vasopressor effect by loxapine.

The possibility of ocular toxicity from loxapine cannot be excluded at this time. Therefore, careful observation should be made for pigmentary retinopathy and lenticular pigmentation since these have been observed in some patients receiving certain other antipsychotic drugs for prolonged periods.

Because of possible anticholinergic action, the drug should be used cautiously in patients with glaucoma or a tendency to urinary retention, particularly with concomitant administration of anticholinergic-type antiparkinson medication.

ADVERSE REACTIONS

CNS Effects: Manifestations of adverse effects on the central nervous system, other than extrapyramidal effects, have been seen infrequently. Drowsiness, usually mild, may occur at the beginning of therapy or when dosage is increased.

It usually subsides with continued LOXITANE therapy. The incidence of sedation has been less than that of certain aliphatic phenothiazines and slightly more than the piperazine phenothiazines. Dizziness, faintness, staggering gait, muscle twitching, weakness, and confusional states have been reported.

Extrapyramidal Reactions—Neuromuscular (extrapyramidal) reactions during the administration of LOXITANE C *loxapine hydrochloride* have been reported frequently, often during the first few days of treatment. In most patients, these reactions involved Parkinson-like symptoms such as tremor, rigidity, excessive salivation, and masked facies. Akathisia (motor restlessness) also has been reported relatively frequently. These symptoms are usually not severe and can be controlled by reduction of LOXITANE dosage or by administration of antiparkinson drugs in usual dosage. Dystonic and dyskinetic reactions have occurred less frequently, but may be more severe. Dystonias include spasms of muscles of the neck and face, tongue protrusion, and oculogyric movement. Dyskinetic reaction has been described in the form of choreo-athetoid movements. These reactions sometimes require reduction or temporary withdrawal of LOXITANE dosage in addition to appropriate counteractive drugs.

Persistent Tardive Dyskinesia—As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movement of the tongue, face, mouth, or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinson agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Cardiovascular Effects: Tachycardia, hypotension, hypertension, lightheadedness, and syncope have been reported.

A few cases of ECG changes similar to those seen with phenothiazines have been reported. It is not known whether these were related to loxapine administration.

Skin: Dermatitis, edema (puffiness of face), pruritus, and seborrhea have been reported with loxapine. The possibility of photosensitivity and/or phototoxicity occurring has not been excluded; skin rashes of uncertain etiology have been observed in a few patients during hot summer months.

Endocrine Effects: No endocrine abnormalities have been reported.

Anticholinergic Effects: Dry mouth, nasal congestion, constipation, and blurred vision have occurred; these are more likely to occur with concomitant use of antiparkinson agents.

Other Adverse Reactions: Nausea, vomiting, weight gain, weight loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, and polydipsia have been reported in some patients.

DOSAGE AND ADMINISTRATION

LOXITANE C *loxapine hydrochloride* is administered orally usually in divided doses two to four times a day. Daily dosage (in terms of base equivalents) should be adjusted to the individual patient's needs as assessed by the severity of symptoms and previous history of response to antipsychotic drugs. Initial dosage of 10 mg twice daily is recommended, although in severely disturbed patients initial dosage up to a total of 50 mg daily may be desirable. Dosage should then be increased fairly rapidly over the first seven to ten days until there is effective control of psychotic symptoms. The usual therapeutic and maintenance range is 60 mg to 100 mg daily. However, as with other antipsychotic drugs, some patients respond to lower dosage and others require higher dosage for optimal benefit. Daily dosage higher than 250 mg is not recommended. For maintenance therapy, dosage should be reduced to the lowest level compatible with symptom control; many patients have been maintained satisfactorily at dosages in the range of 20 mg to 60 mg daily.

LOXITANE C Oral Concentrate should be mixed with orange or grapefruit juice shortly before administration.

Use only the enclosed calibrated (10 mg, 15 mg, 20 mg, 25 mg) dropper for dosage.

HOW SUPPLIED

LOXITANE C *loxapine hydrochloride* is supplied in bottles of 4 fl. oz. (120 ml) with calibrated dropper. Each ml contains the equivalent of 25 mg loxapine base as the HCl. Rev 4/76

The familiar refrain of depression: morning fatigue... sadness... anorexia... insomnia

Now, Merrell offers Norpramin (desipramine hydrochloride tablets N.F.) to effectively relieve these common manifestations of depression.

Norpramin also provides additional benefits in treatment of your patients.

- ☐ effectively relieves physical, psychological and emotional symptoms of depression
- ☐ minimal daytime sedation — important for patients who must be alert to perform daytime activities
- ☐ relief that may begin in 2 to 5 days — but full therapeutic effect is seldom seen before 2 weeks
- ☐ side effects rarely require discontinuation of therapy
- ☐ increases interpersonal responsiveness
- ☐ can help facilitate psychotherapy

Prescribe Norpramin to change the familiar refrain of depression in your practice.

Norpramin®
(desipramine hydrochloride tablets N.F.)

Brief Summary
Indications: Norpramin (desipramine hydrochloride tablets N.F.) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.
Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.
Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease. (b) with a history of urinary retention or glaucoma. (c) with thyroid disease or those on thyroid medication. (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.
Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. If possible, dispense in child-resistant containers. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosis in schizophrenic patients. Use cautiously with anticholinergic or sympathomimetic drugs. Response to alcoholic beverages may be exaggerated. In the concurrent administration of ECT and antidepressant drugs one should consider the possibility of increased risk relative to benefits. Discontinue as soon as possible prior to elective surgery because of possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients on desipramine hydrochloride. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy: the drug should be discontinued if there is neutropenia.
Adverse Reactions: *Cardiovascular:* hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke. *Psychiatric:* confusional states (especially in the elderly), hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever, cross sensitivity with other tricyclic drugs. *Hematologic:* bone marrow depressions including agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss, perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.
Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily; increase to 100 mg. daily if necessary.
Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.

The schools don't like to get involved with medication for MBI –and now they don't have to

Importance of Cylert (pemoline) single daily dosage to the child, the parents and the teacher

For the child		For the adults
No drug in child's possession while at school	⟷	Control of medication remains with parents
Avoids situation in which child is repeatedly singled out as being "different"	⟷	Obviates need for teacher or nurse to supervise taking of mid-day doses
Helps prevent possible variations in effect caused by missed, forgotten or delayed doses	⟷	Helps assure that the prescribed dosage is being given each day

Cylert offers these benefits in a treatment program for MBD

- Single daily dose administration
- Minimal cardiovascular effects
- Mean dosage in long-term studies remained remarkably constant
- Can be taken with breakfast

Cylert® (pemoline) CIV

dosage is once-a-day, given to the child at home by the parent

Cylert, alone among CNS stimulants used to treat MBD, is inherently long-acting, permitting once-daily dosage

Dosage and administration

Cylert is given as a single oral dose each morning.

The recommended starting dose is 37.5 mg. per day. This daily dosage should be gradually increased at one-week intervals using increments of 18.75 mg. until the desired clinical response is obtained.

The mean daily effective dose ranges from 56.25 to 75 mg. per day. The maximum recommended daily dose of Cylert is 112.5 mg.

Using the recommended schedule of dose titration, significant benefits may not be seen until the third or fourth week of drug therapy. Side effects may be seen prior to optimum clinical results.

When not to use Cylert

Cylert should not be used for (and will not be effective in) simple cases of overactivity in school age children.

Neither should it be used in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

The physician should rely on a complete history of the child and a thorough description of symptoms from both parents and teacher before postulating a diagnosis of MBD.

Please see next page for Prescribing Information

6083144

Cylert®
(pemoline) CIV

Prescribing Information

Description: Cylert (pemoline) is a white, tasteless, odorless powder which is relatively insoluble (less than 1 mg/ml) in water, chloroform, ether, acetone, and benzene. In 95% ethyl alcohol, the solubility of pemoline is 2.2 mg/ml.

Actions: Cylert (pemoline) is a central nervous system stimulant. The pharmacologic activity of pemoline is similar to that of other known stimulants but with minimal sympathomimetic effects. Pemoline is structurally dissimilar from the amphetamines and methylphenidate. Although the exact mode of pharmacodynamic action is undetermined in man, pemoline has been reported to increase the rate of synthesis of dopamine in rat brain.

In human subjects, Cylert produces peak blood levels within 2-4 hours. The serum half-life is approximately 12 hours. Multiple dose studies in adults at several dose levels indicate that serum levels plateau in approximately three days. Cylert and its metabolites are primarily excreted by the kidneys with approximately 75% of an oral dose appearing in the urine within a 24-hour period. Approximately 43% of pemoline is excreted unchanged. Metabolites include pemoline dione, conjugated pemoline and mandelic acid.

Cylert (pemoline) has a gradual onset of action in children with minimal brain dysfunction. Using the recommended schedule of dosage titration, significant clinical benefit may not be evident until the third or fourth week of drug administration.

Indications: MINIMAL BRAIN DYSFUNCTION IN CHILDREN—as adjunctive therapy to other remedial measures (psychological, educational, social).

Special Diagnostic Considerations:

Specific etiology of minimal brain dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis includes the use not only of medical but of psychological, educational, and social resources.

Characteristics commonly reported include: A chronic history of moderate to severe hyperactivity, short attention span, distractibility, emotional lability, and impulsivity. Nonlocalizing (soft) neurological signs, learning disability, and abnormal EEG may or may not be present. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. In the primary therapy of MBD, appropriate educational placement is essential and psychosocial intervention is generally necessary. When these measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

Contraindication: Cylert (pemoline) is contraindicated in patients with known hypersensitivity or idiosyncrasy to the drug. (See PRECAUTIONS)

Warnings: Cylert is not recommended for children under six years of age since safety and efficacy in this age group have not yet been established.

Since Cylert (pemoline) and its metabolites are excreted primarily by the kidneys, caution should be observed in administering the drug to children with significantly impaired renal function.

Sufficient data on safety and efficacy of Cylert administration for periods beyond two years duration in children with minimal brain dysfunction are not yet available. Although a definite causal relationship has not been established, some temporary suppression of predicted growth pattern(i.e., weight and/or height) has been reported with the long-term use of stimulants in children. Therefore, patients requiring long-term therapy should be carefully monitored.

Drug Interactions: Interactions between Cylert and other drugs have not been studied in humans. As with most other drugs, concurrent administration with other agents, especially drugs with central nervous system activity, should be carefully monitored.

Usage in Pregnancy: Safety for use in pregnancy has not been established. Standard studies of fertility, teratology and reproduction were conducted in rats and rabbits. Daily oral doses of pemoline of 18.75 and 37.5 mg/kg beginning at conception produced no abnormalities in the fetuses and did not affect viability at birth. Further studies using similar dose levels with drug administration beginning 14 days before conception demonstrated an increased incidence of stillbirths in these animals.

Drug Dependence: Studies of the drug abuse potential of Cylert (pemoline) in primates have not demonstrated a potential for self-administration. However, the pharmacologic similarities between Cylert and other CNS stimulants with known abuse liability suggest that drug dependence of the stimulant type might occur. There have been isolated reports of transient psychotic symptoms in adults following long-term misuse of pemoline taken orally in excessive quantities. Therefore, caution should be observed in emotionally unstable patients considered to have a psychological potential for drug dependence.

Precautions: Delayed hypersensitivity reactions involving the liver have been reported in 1-2% of the patients receiving Cylert usually after several months of therapy. No clinical symptomatology has been observed, but mild to moderate increases in transaminase (SGOT and SGPT) levels have occurred in these cases. These effects appear to be completely reversible when drug treatment is discontinued. Transaminase levels should be determined periodically during therapy with Cylert to detect any such reactions.

Adverse Reactions: The most frequently reported adverse reaction with Cylert is insomnia. Insomnia has been observed prior to optimum therapeutic response and in the majority of cases was transient in nature or responded to dosage reduction. Anorexia with weight loss during the first few weeks of therapy has also been reported. With continuing therapy, a return to a normal weight curve usually occurred within three to six months. Other adverse reactions reported include stomachache, skin rash, irritability, mild depression, nausea, dizziness, headache, drowsiness, and hallucinations. Mild adverse reactions appearing early in treatment often remit with continuing therapy. If adverse reactions are of a significant or protracted nature, dosage reduction or discontinuation should be considered.

Dosage and Administration: Cylert (pemoline) is administered as a single oral dose each morning. The recommended starting dose is 37.5 mg per day. This daily dosage should be gradually increased at one week intervals using increments of 18.75 mg until the desired clinical response is obtained. The mean daily effective dose ranges from 56.25 to 75 mg per day. The maximum recommended daily dose of pemoline is 112.5 mg.

Clinical improvement with Cylert is gradual. Using the recommended schedule of dosage titration, significant benefit may not be evident until the third or fourth week of drug administration. Drug administration should be interrupted occasionally to determine if behavioral symptoms sufficient to require continuing therapy recur.

Overdosage: Cylert overdosage has been reported to produce symptoms of tachycardia, hallucinations, agitation, or restlessness. The treatment of acute massive overdosage with pemoline is essentially the same as that for overdosage with any drug having CNS stimulatory effects. Management is largely symptomatic and may include induction of emesis, gastric lavage or other measures as appropriate.

How Supplied: Cylert (pemoline) is supplied as monogrammed, grooved tablets in three dosage strengths:

18.75 mg. tablets (yellow-colored) in bottles of 100 (**NDC** 0074-6025-13)

37.5 mg. tablets (orange-colored) in bottles of 100 (**NDC** 0074-6057-13)

75 mg. tablets (tan-colored) in bottles of 100 (**NDC** 0074-6073-13)

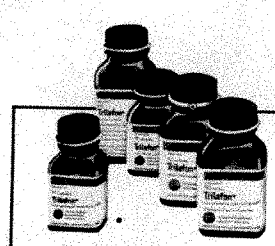
Help restore reality

Trilafon®
brand of
perphenazine, NF

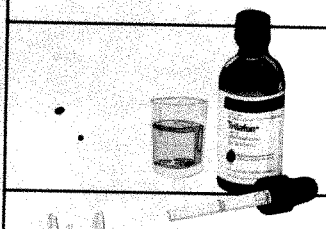
for management of disturbed behavior in schizophrenic and manic states

- low dose, high potency phenothiazine useful for inpatient and outpatient treatment
- helps orient psychiatric patients to their surroundings
- effective with minimal sedation, usually produces little lethargy or drowsiness



Versatile Dosage	
Injection	5 mg/ml, 1 ml ampul
Concentrate	16 mg/5 ml, 120 ml bottle
Tablets	2,4,8,16 mg
REPETABS® Tablets 8 mg brand of repeat-action tablets	

Please see next page for prescribing information.



Trilafon®
brand of perphenazine, NF

For management of schizophrenic and manic disorders in psychiatric hospitals, mental health clinics, and with outpatient treatment

TABLETS
for maintenance or control of patients in hospital or home

BENEFITS
- generally improve cooperation and communication
- decrease need for custodial care, hasten discharge

CONCENTRATE
for maintenance or control of uncooperative in-hospital patients

- easily mixes with most liquids
- ensures easy, steady, certain administration

INJECTION
for emergency control of uncooperative in-hospital patients

- usually takes effect in 10 minutes
- average duration of effect is 6 hours

TRILAFON® Tablets
brand of perphenazine, NF
REPETABS® Tablets
Concentrate
Injection

CONTRAINDICATIONS TRILAFON is contraindicated in drug-associated central nervous system depression (barbiturates, alcohol, narcotics, analgesics, antihistamines). Perphenazine is contraindicated in the presence of existing blood dyscrasias, bone marrow depression and pre-existing liver damage, and in patients who are hypersensitive to perphenazine.

TRILAFON **Injection** should not be given to patients in coma or severely depressed states.

WARNINGS **Dosage in pregnancy:** Perphenazine should only be given to pregnant patients when, in the judgment of the physician, the potential benefits outweigh the possible risks.

Perphenazine can lower the convulsive threshold in susceptible individuals; it should be used with caution in patients with convulsive disorders. If the patient is being treated with an anticonvulsant agent, increased dosage of that agent may be required when perphenazine is used concomitantly.

Perphenazine should be used with caution in patients with psychic depression.

Perphenazine is not recommended for children under 12 years of age.

Perphenazine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or operating machinery.

PRECAUTIONS As with any potent medication, patients receiving perphenazine should be under medical supervision, particularly if they are receiving high doses. Patients who have had any severe reaction to phenothiazines or to imipramine should be treated cautiously, under close medical supervision.

Although the following adverse reactions have not been reported in patients treated with perphenazine, the possibility that they might occur with TRILAFON should be considered: blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, eosinophilia); liver damage (biliary stasis); narrowing of the visual fields; pigmentation of the retina, cornea, or lens; cerebral edema; polyphagia; photophobia; hyperpyrexia.

If hypotension develops, levarterenol (norepinephrine) can be used, but not epinephrine, because epinephrine's action is blocked and partly reversed by perphenazine. Severe, acute hypotension has occurred with the use of phenothiazines and is of particular concern in patients with mitral insufficiency or pheochromocytoma.

A significant rise in body temperature may indicate an idiosyncratic reaction to perphenazine; treatment with perphenazine should be stopped if this occurs.

The antiemetic effect of perphenazine can obscure signs of toxicity due to overdosage of other drugs, or mask the symptoms of disease (eg, brain tumor or intestinal obstruction).

Contact dermatitis has been reported with a perphenazine solution; therefore, contact of hands or clothing by those handling perphenazine solutions should be avoided.

POTENTIATION Since phenothiazines can potentiate the central-nervous-system-depressant actions of opiates, antihistamines, barbiturates, and alcohol, less than the usual dosage of these agents is required when they are administered concomitantly with TRILAFON. Patients should be cautioned that their response to alcohol may be increased while they are being treated with TRILAFON.

Phenothiazines also potentiate the effects of atropine, heat, and phosphorus insecticides, and should be used with caution in persons exposed to these agents.

ADVERSE REACTIONS *Extrapyramidal reactions:* dystonia including protrusion, discoloration, aching and rounding of the tongue; tonic spasm of the masticatory muscles; tight feeling in the throat, slurred speech, dysphagia, oculogyric crisis, trismus, torticollis, retrocollis, muscle weakness, and aching and numbness of the limbs; akathisia; motor restlessness; dyskinesia, parkinsonism; hyperreflexia; and ataxia. The incidence and severity of these reactions usually increase with increased dosage, but have occurred in some patients receiving low dosage. Reduction in dosage or treatment with an antispasmodic agent will usually control extrapyramidal reactions. In some instances, however, these reactions may persist after discontinuation of treatment with perphenazine.

Persistent tardive dyskinesia: As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities. There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine, vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Allergic reactions: erythema, pruritus, urticaria, eczema, anaphylactoid reactions, and local and generalized edema. In extremely rare instances, individual idiosyncrasy or hypersensitivity to phenothiazines has resulted in cerebral edema, circulatory collapse, and death. Photosensitization, asthma, and exfoliative dermatitis have also occurred in patients treated with phenothiazines.

Autonomic reactions: blurred vision, dry mouth or salivation, nasal congestion, nausea, vomiting, hypertension, tachycardia, hypotension, anorexia, urinary frequency or incontinence, and constipation. Significant autonomic effects have been infrequent in patients receiving less than 24 mg. perphenazine daily.

Other reactions: endocrine disturbances (lactation, gynecomastia, galactorrhea, disturbances in the menstrual cycle), headaches, mild insomnia, altered cerebrospinal fluid proteins, ECG abnormalities, reactivation of psychosis, paradoxical excitement, paranoid-like reactions, catatonia, and systemic lupus erythematosus-like syndrome. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active. The following adverse reactions, though rare, have also been reported to be associated with perphenazine treatment: agranulocytosis; jaundice; hyperpigmentation of the skin; grand mal convulsions; failure of ejaculation; hyperglycemia.

Side effects with intramuscular TRILAFON **Injection** have been infrequent and transient. Dizziness or significant hypotension after treatment with TRILAFON (perphenazine) **Injection** is a rare occurrence.

CHARLES C THOMAS · PUBLISHER

PHILOSOPHICAL DIMENSIONS OF PARAPSYCHOLOGY *edited by* **James M. O. Wheatley**, *Univ. of Toronto, Toronto, Canada, and* **Hoyt L. Edge**, *Rollins College, Winter Park, Florida. (22 Contributors)* Traditional philosophical issues are re-examined and novel problems arising from advances in the field are critically discussed. Divided into five sections, the readings range over such topics as the philosophical relevance of parapsychology; knowledge, memory and ESP; paranormal precognition; personal survival of bodily death; and the relationship between science and the paranormal. *'76, 520 pp., 3 il., $24.50*

CRISIS SERVICES FOR CAMPUS AND COMMUNITY: A Handbook for the Volunteer *by* **E. Robert Sinnett**, *Kansas State Univ., Manhattan. In collaboration with* **Cecil J. Killacky, Anthony P. Jurich, Marylyde Kornfeld, Orma Linford, Kathleen Keen Sinnett** *and* **Nancy Burnett**. *Foreword by* **Edward D. Greenwood**. Areas of key concern in dealing with youth and young adults are highlighted in this book including how to develop a helping relationship and assistance with emotional problems, suicidal tendencies, difficulties in dealing with sexuality, and drug abuse; how to aid in defense and advocacy; and how to make and handle referrals. *'76, 260 pp., 5 il., 12 tables, $12.50*

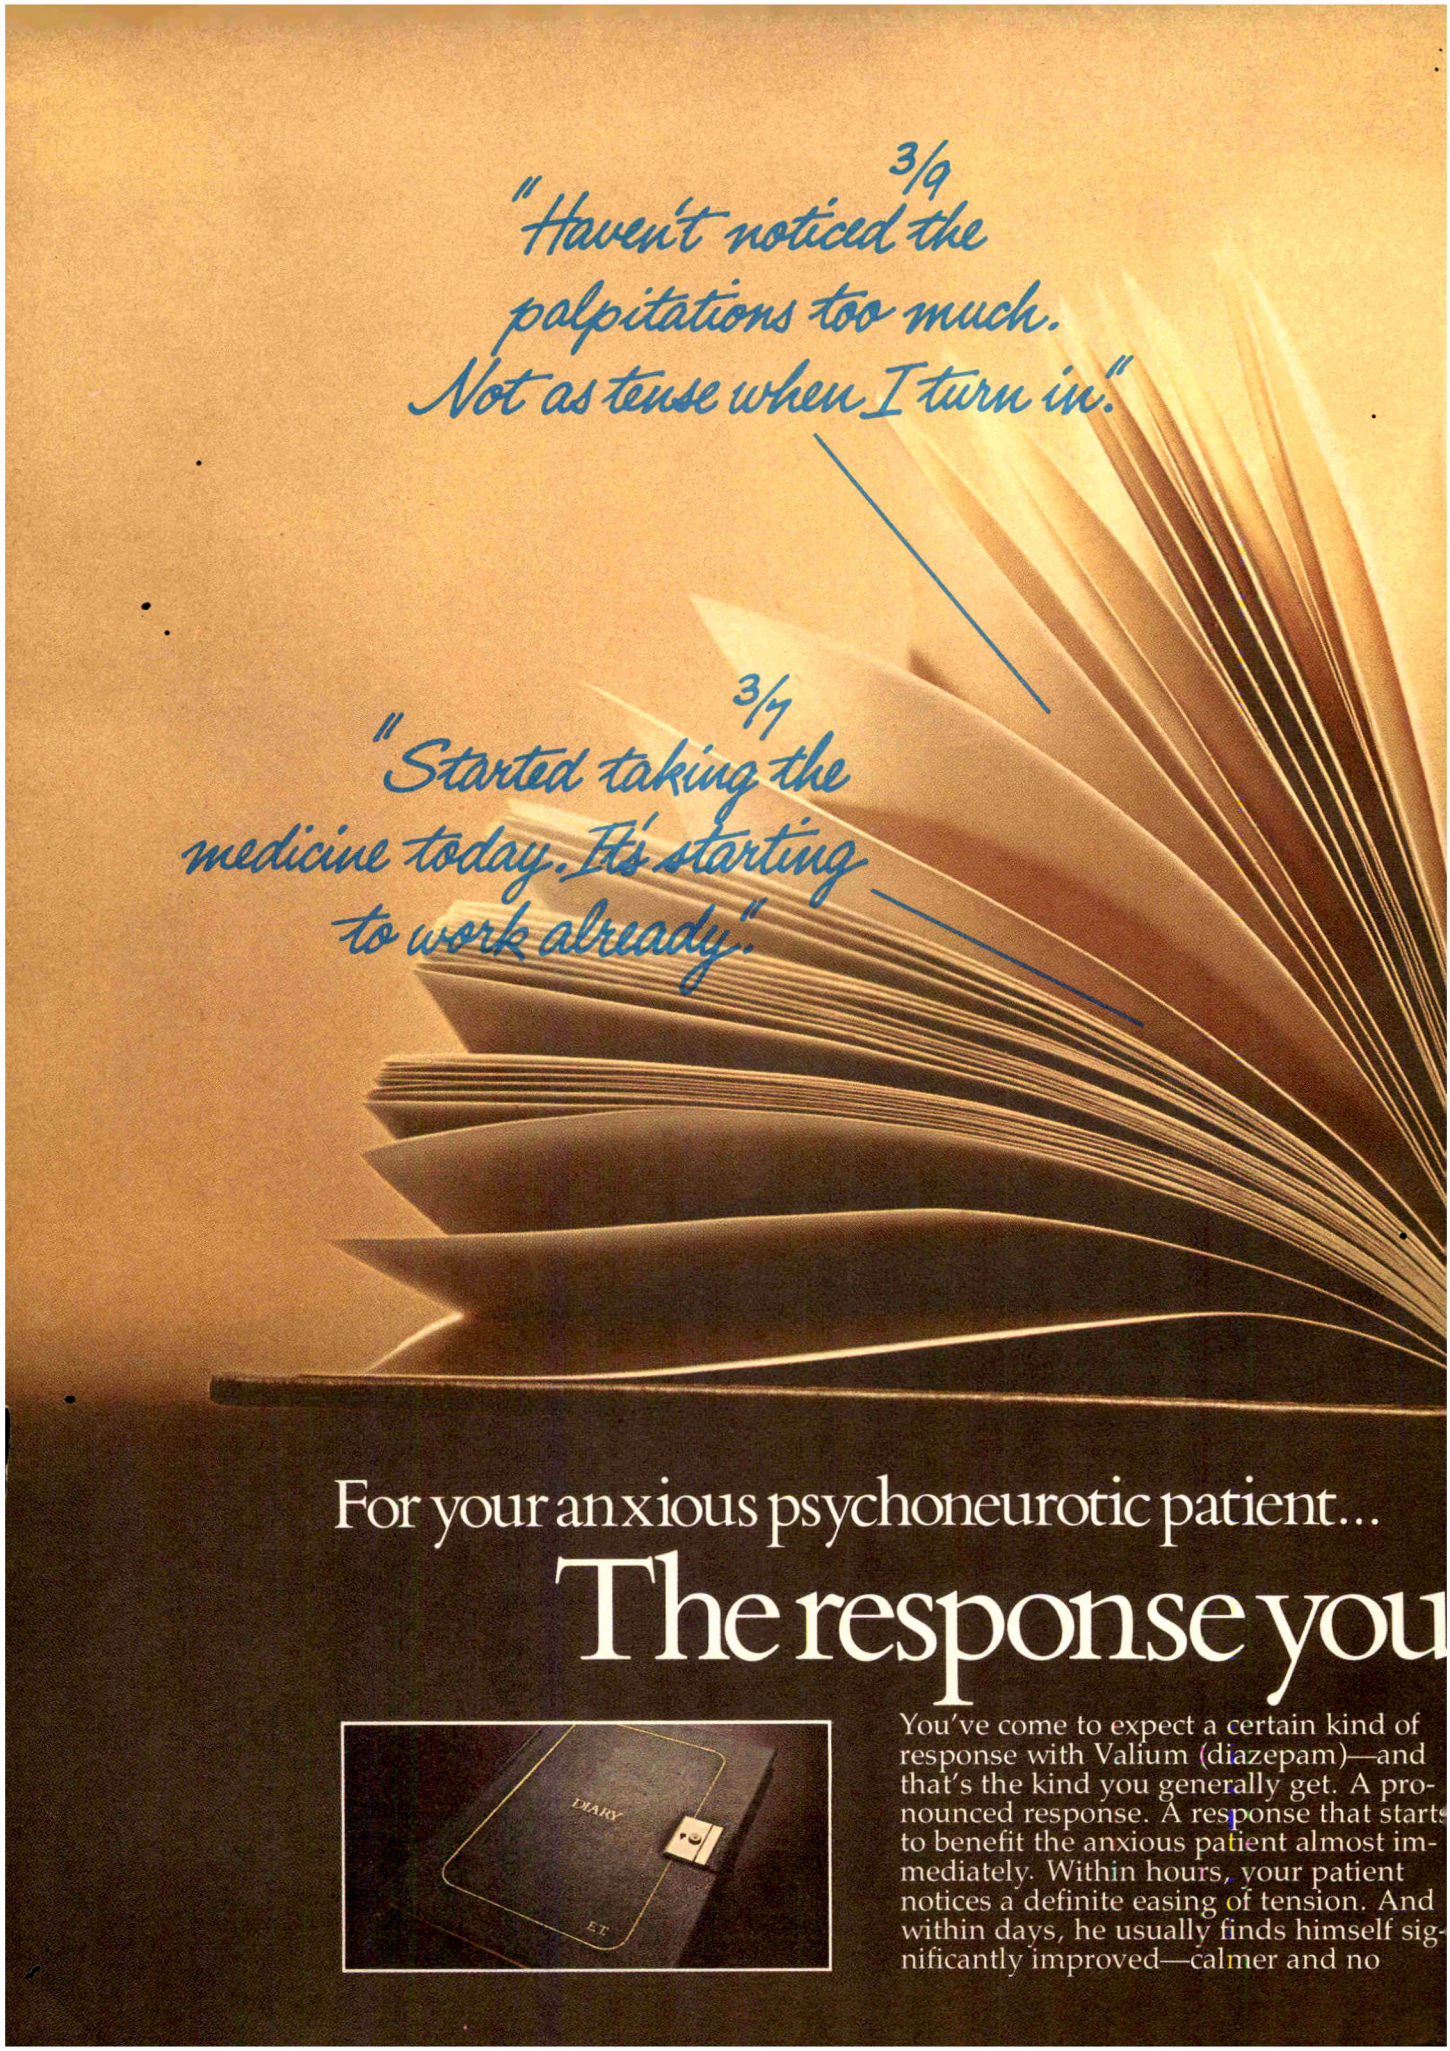
ACUTE GRIEF AND THE FUNERAL *edited by* **Vanderlyn R. Pine, Austin H. Kutscher, David Peretz, Robert C. Slater, Robert DeBellis, Robert J. Volk,** *and* **Daniel J. Cherico**. This volume comprehensively describes the psychological and social impact of bereavement during the period of acute grief, the time that encompasses those events immediately following the death of a significant and loved individual. Of particular interest are chapters on explaining death to children, the impact of social neglect on the elderly, and the roles of the funeral director, psychiatrist, educator and minister in giving counsel to the bereaved. *'76, 328 pp., 1 il., 26 tables, $16.50*

HOMINOLOGY: PSYCHIATRY'S NEWEST FRONTIER *by* **C. David Jones**, *Chicago Medical School, Chicago, Illinois.* This book details the fallacies inherent in both the absolute and relativistic version of moral values. It also presents a fascinating history of hominology and explains how a simplified form is being utilized with culturally different children to help them gain a sense of personal dignity and enhance their self-image. *'75, 216 pp., 15 il., 2 tables, $12.50*

MENTAL EXAMINER'S SOURCE BOOK *edited by* **Julian C. Davis**, *Florida State Hospital, Chattahoochee, and* **John P. Foreyt**, *Baylor College of Medicine, Houston, Texas. (11 Contributors)* Authoritative material is provided on both traditional mental evaluation instruments and recent topics in clinical assessment. Along with chapters on the classification of mental retardation, objective and projective personality testing, assessment of brain damage, intelligence testing and the mental status examination, there are chapters on the psychological evaluation of coronary heart disease, and pain and disability. *'75, 248 pp., 18 il. (5 in color), 37 tables, $14.50*

THE EVOLUTION AND CHEMISTRY OF AGGRESSION *by* **Delbert D. Thiessen**, *Univ. of Texas, Austin. Foreword by* **I. Newton Kugelmass**. While it is possible to investigate one facet independently of the other, the two, evolution and chemistry, are intimately intertwined and are best studied together. Emphasis is placed on understanding the biochemical processes underlying aggression. The author explores the phylogenetic history of aggression, outlines several genetic correlates of aggression, examines hormonal control, reviews the significance of chemosignals, and discusses brain biochemistry. *'76, 232 pp., 38 il., 27 tables, $18.50*

CASE STUDIES OF THE CLINICAL INTERPRETATION OF THE BENDER GESTALT TEST: Illustrations of the Interpretive Process for Graduate Training and Continuing Professional Education *by* **Clifford M. DeCato** *and* **Robert J. Wicks**, *both of Hahnemann Medical College and Hospital, Philadelphia, Pennsylvania. Foreword by* **Zygmunt A. Piotrowski**. The emphasis of this work is placed on illustrating a strategy by which a clinician can derive inferences from the Bender Gestalt Test to arrive at clinically useful formulations of personality development. The book features both child and adult cases, illustrations of the projective uses of BGT, and a substantive bibliography. *'76, 152 pp., 31 il., $9.75*



HYPNOSIS AND BEHAVIOR THERAPY *edited by* **Edward Dengrove**. *(42 Contributors)* Hypnosis can produce conditions most like real life and can make treatment easier by relaxing the patient, easing the path to visual imagery and providing techniques which aid in the management of the more difficult patients. Following an introductory section defining behavior therapy and hypnosis, a section devoted to experiments deals with the effects of hypnosis on conditionability and other basic phenomena underlying behavior therapy. A section is included describing the use of behavior therapy techniques in hypnotherapy. *'76, 428 pp., 30 il., 6 tables, $26.75*

EMERGENCIES IN CHILD PSYCHIATRY: Emotional Crises of Children, Youth and Their Families *edited by* **Gilbert C. Morrison**, *Univ. of California, Irvine. Foreword by* **Louis A. Gottschalk**. *(21 Contributors)* Clinical problems and clinical findings are defined in this book, treatment approaches proposed, theoretical understanding outlined, and possible research methodologies detailed. *'75, 516 pp., 33 tables, $24.50*

A VIEW INTO A MODERN, STATE-OPERATED, MENTAL HEALTH FACILITY: The Madden Zone Center *edited by* **Robert A. deVito** *and* **Richard P. Tapley**, *both of Madden Zone Center, Hines, Illinois. (47 Contributors)* Residential, day care and outpatient psychiatric treatment programs provided by the community-oriented state mental health facility are described in this book. Services for mentally ill adults and children as well as family-oriented behavior modification programs for developmentally disabled children and adolescents are described. *'75, 308 pp., 16 tables, $19.75*

2-mg, 5-mg, 10-mg scored tablets

Initial calming in hours.

Your anxious psychoneurotic patient will find the prompt action of Valium highly reassuring. It's immediate, tangible proof that his medication is working.

Significant improvement in days

As Valium reduces overwhelming symptoms of anxiety and psychic tension, your patient begins to feel better often within a few days.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders; athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10.

a valuable link to the resources of the American Psychiatric Association

for institutions and agencies concerned with the care of the mentally disabled

Enrollment in the Hospital & Community Psychiatry Service brings multiple copies of *Hospital & Community Psychiatry* into member agencies every month, keeping staff up to date on developments and issues in the mental health field, offering new ideas and fresh perspectives, and serving as a useful resource in staff development and training programs.

Hospital & Community Psychiatry is just one of the benefits of membership in the H&CP Service. Others include a film library containing more than a hundred films specially chosen for their usefulness in staff development and community education programs; supplementary mailings of important books, reports, articles, or other material of special interest to administrators or clinicians; reduced registration fees at the annual fall Institute on Hospital & Community Psychiatry; and, on request, information and consultation from the professional staff of the American Psychiatric Association. The H&CP Service also sponsors the annual Achievement Awards competition, which gives special recognition to outstanding programs for the mentally ill and mentally retarded.

Please send me information about membership in the Hospital & Community Psychiatry Service.

The vulnerable ages

The first epileptic seizure is most likely to occur during early childhood and at the onset of puberty

About 9 out of 10 epileptics experience their first seizure before the age of 20—with the highest incidence between 5 and 7, when children start school, and at the onset of puberty, a time of physiological and psychic turmoil.[1] The most common type, grand mal, occurs in approximately 75% of epileptic children,[1] and more than 50% of patients who suffer initially from petit mal develop grand mal seizures before they reach the age of 16.[2]

Mysoline (primidone) for control of grand mal, psychomotor and focal epilepsy

At the onset and afterwards — used alone or as concomitant therapy, MYSOLINE may reduce the frequency and severity of major motor seizures—or even eliminate them. *Excellent* for control of grand mal. Valuable for control of psychomotor[1,3,4] and focal epilepsy as well.[5]

Add Mysoline when control with other anticonvulsants is inadequate — As concomitant therapy, MYSOLINE can improve seizure control in grand mal and psychomotor epilepsy. The combined use of phenobarbital, diphenylhydantoin, and MYSOLINE may have additive anticonvulsant effects without additive side effects.[6]

Change to Mysoline when other anticonvulsants fail — A changeover to MYSOLINE is frequently warranted when other anticonvulsants must be discontinued because of important side effects, or when grand mal seizures are refractory to phenobarbital, with or without diphenylhydantoin.[7]

Mysoline® (primidone)

may be the start of a better life for the epileptic

initial and maintenance therapy for
grand mal, psychomotor and focal epilepsy

BRIEF SUMMARY
(For full prescribing information, see package circular.)

MYSOLINE® Brand of PRIMIDONE
Anticonvulsant

ACTIONS: MYSOLINE acts on the central nervous system to raise seizure threshold or alter seizure pattern. The mechanism(s) of action of anticonvulsant drugs is not known.

Primidone has anticonvulsant activity *per se*. In addition, its two metabolites possess anticonvulsant qualities. The major metabolite is phenylethylmalonamide (PEMA); the other is phenobarbital. In addition to its own anticonvulsant potential, PEMA potentiates phenobarbital.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several days before it can be assessed.

Use in pregnancy: Recent reports strongly suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Reference has been made to primidone in several cases in which it was used *in combination* with other anticonvulsants; but its teratogenicity has not been conclusively demonstrated. The possibility exists that other factors, *e.g.*, genetic factors or the epileptic condition, may contribute to the higher incidence of birth defects. The data also indicate that the great majority of mothers receiving anticonvulsant medication deliver normal infants.

Anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and risk to both mother and the unborn child.

When the nature, frequency, and severity of the seizures do not pose a clear threat to the patient, good medical practice requires that the physician weigh the expected therapeutic benefit of anticonvulsant therapy against possible risk on an individual basis.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

The physician should weigh all of the foregoing considerations when treating and counseling epileptic women of childbearing potential.

PRECAUTIONS: The total daily dosage should not exceed 2 Gm. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

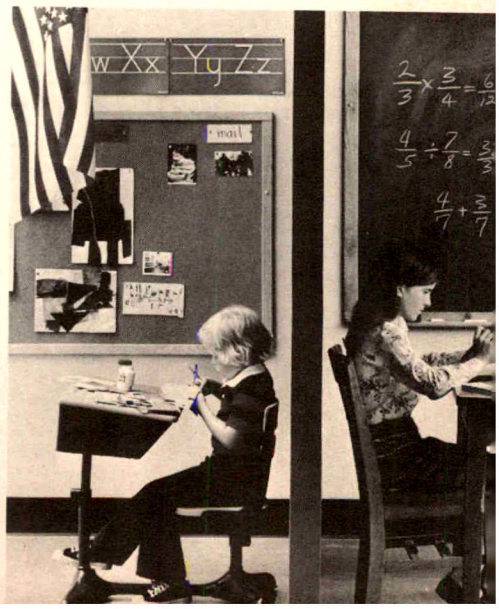
ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid, 15 mg. daily, without necessity of discontinui medication.

DOSAGE AND ADMINISTRATION: The avera adult dose is 0.75 to 1.5 Gm. per day. The initial dose is 250 r Increments of 250 mg. are added, usually at weekly interv to tolerance, or therapeutic effectiveness, up to daily doses n exceeding 2.0 Gm. A typical dosage schedule for the introd tion of MYSOLINE (primidone) is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg. daily at bedtime	*2nd Week* 250 mg. b.i.d.
3rd Week 250 mg. t.i.d.	*4th Week* 250 mg. q.i.d.

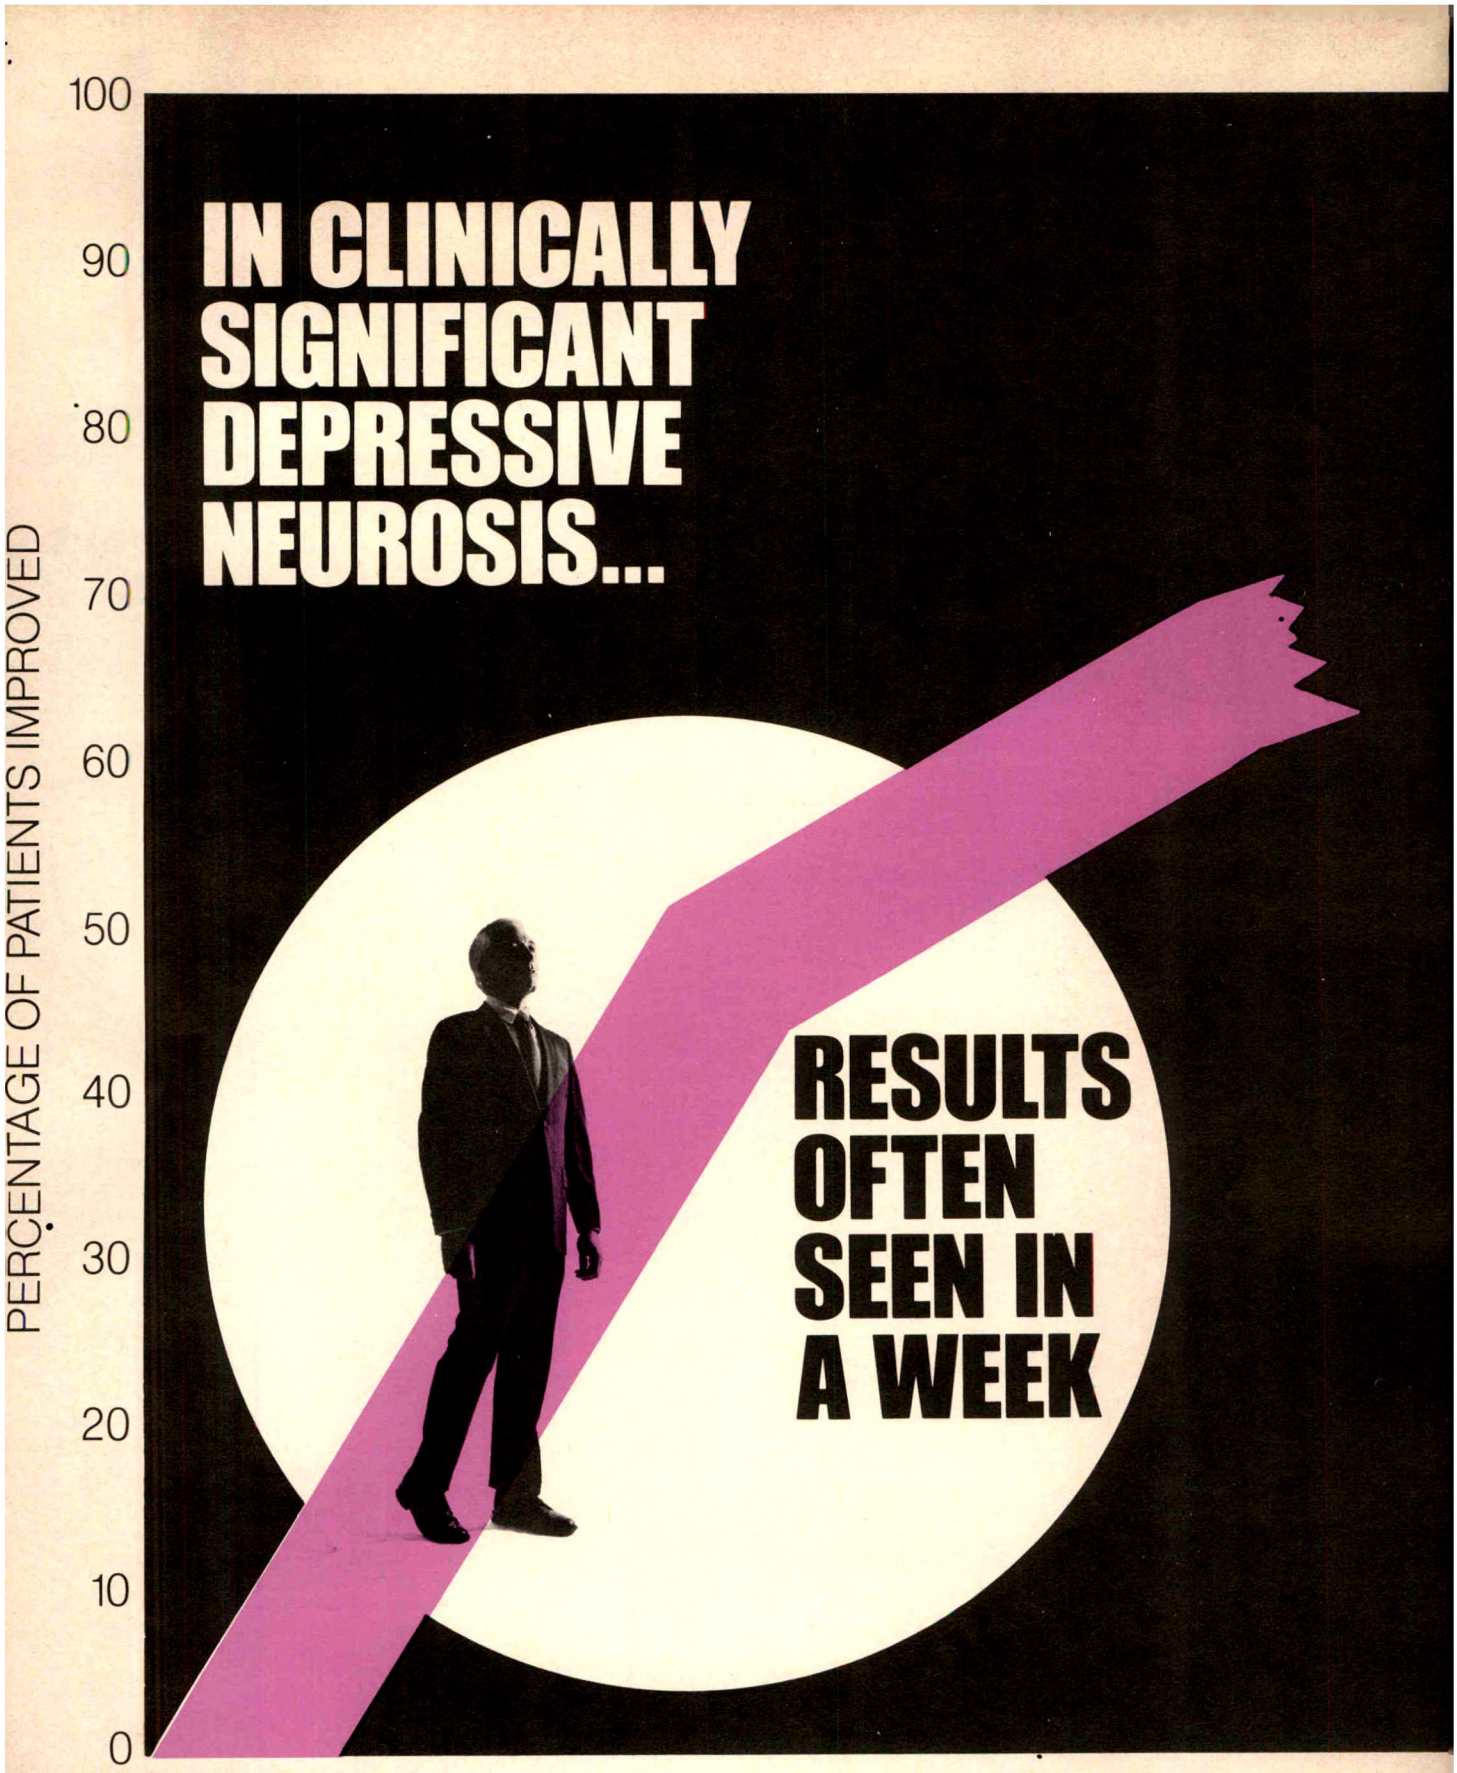
In children under 8 years of age, maintenance levels are e tablished by a similar schedule, but at one-half the adult dosa It is best to begin with 125 mg., with gradual weekly increas of 125 mg. a day, to a daily total usually between 500 mg. ar 750 mg.



In patients already receiving other anticonvulsant MYSOLINE should be gradually increased as dosage of tl other drug(s) is maintained or gradually decreased. This re men should be continued until satisfactory dosage level achieved for combination, or the other medication is complete withdrawn. When therapy with this product alone the objective, the transition should not be completed in le than two weeks.

MYSOLINE 50 mg. Tablet can be used to practical advantag when small fractional adjustments (upward or downwar may be required, as in the following circumstances:

- for initiation of combination therapy
- during "transfer" therapy
- for added protection in periods of stress or stressful situ tions that are likely to precipitate seizures (menstruatio allergic episodes, holidays, etc.)



HOW SUPPLIED: MYSOLINE *Tablets*—No. 430—Eac tablet contains 250 mg. of primidone (scored), in bottles o 100 and 1,000. Also in unit dose package of 100. No. 431—Eac tablet contains 50 mg. of primidone (scored), in bottles of 10 and 500. MYSOLINE *Suspension*—No. 3850—Each 5 cc. (te spoonful) contains 250 mg. of primidone, in bottles of 8 fluic ounces.

IN CLINICALLY SIGNIFICANT DEPRESSIVE NEUROSIS...

SANDOZ SAN 6-598

For details of study and brief summary, please see following page.

Mellaril (thioridazine) can help you cope with the problem of depressive neurosis because it often produces measurable improvement by the end of the first week of therapy. In 14 double-blind studies, 339 patients with depressive neurosis received Mellaril for four weeks. In these studies, 174 patients (51.3%) improved measurably by the end of the first week, and a total of 293 (86.4%) improved during the four weeks of therapy. Furthermore, 55% of the overall improvement was observed by the end of the first week.

Mellaril usually does not cause euphoria or undue sedation and is not habituating. Patients, therefore, generally remain alert and better able to respond to therapy. (The physician should, however, caution patients against participating in activities which require complete mental alertness, e.g., driving.)

MELLARIL®
(thioridazine)

TABLETS: 10 mg, 15 mg, 25 mg, and 50 mg thioridazine HCl, U.S.P.

for the short-term treatment of moderate to marked depression with variable degrees of anxiety in patients with depressive neurosis

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

Dosage: Dosage must be individualized according to the degree of mental and emotional disturbance, and the smallest effective dosage should be determined for each patient. In adults with depressive neurosis the usual starting dosage is 25 mg t.i.d. and the dosage ranges from 10 mg b.i.d. to q.i.d. in milder cases to 50 mg t.i.d. or q.i.d. for more severely disturbed patients; the total daily dose ranges from 20 mg to a maximum of 200 mg.

THE AMERICAN JOURNAL OF PSYCHIATRY

Overview: Psychiatric Sequelae to Multiple Trauma

BY NATHAN SCHNAPER, M.D., AND R ADAMS COWLEY, M.D.

The authors discuss the setting, patients, and staff, and the role of psychiatric consultants in intensive care units and trauma centers. They point out the similarities and differences between patients with multiple trauma and those who have had open-heart surgery and head or spinal cord injuries. They also deal with the question of an element of self-destructive behavior in accidents and offer suggestions for the psychiatric management of severely traumatized patients. The authors conclude that the role and obligation of the psychiatrist of the future will lie in crisis intervention within the medical-biological model.

A SEARCH OF THE LITERATURE reveals a paucity of information on the psychological implications of multiple trauma. It appears that professional concern for multiple trauma is limited to medical and surgical journals. We found only one article (1) that mentioned multiple injuries (only incidentally) and only one article (2) that included the term "severe trauma" in its title (written by one of us [N.S.]).

The literature on the relationship between general medicine and psychiatry deals with the emotional problems seen in intensive care units (ICUs) and those associated with medical and surgical illnesses. The usual approach involves investigation of the psychological ramifications of illnesses involving a single organ. Open-heart surgery and its psychiatric sequelae command the most attention; head and spinal cord injuries command less. Although there are marked clinical differences between these difficulties and multiple trauma, their similarities in terms of intensive care and psychiatric complications require that they be included in this discussion.

In this overview we will discuss the setting for treatment of multiple trauma, the patients, the staff, and the role of the psychiatric consultant. These separations, of course, are artificial; the interactions among them are as intense as they are important. We will also discuss the psychological implications of accidents and make some suggestions for management of patients with multiple trauma.

THE SETTING

There are many and varied types of ICUs. They include surgical, medical, coronary care, stroke, pediatric, burn, neurological, and others. Most ICUs are windowless, impersonal, highly mechanized (including electronic monitors), and overloaded with auditory and visual stimuli (3–8)—much like a "science fiction atmosphere" (6) or a "tension-charged strategic war bunker" (9). The psychological symptoms of patients subjected to this environment run the gamut of depression, delirium, hallucinations, delusions, neurosis, and psychosis. Aggressive in its therapeutic efforts, the ICU is housed in one area, and its patients are usually in-hospital transfers with established diagnoses.

In contrast, trauma victims are admitted to an emergency room, where diagnosis, investigation, and surgery invariably require their being transported to distant operating rooms (assuming the facilities are available and staffed). Recently, a new concept has been developed: the trauma center. This is a combined first-contact emergency department and ICU. The patient arrives undiagnosed and untreated directly from outside the hospital complex. Treatment demands a variety of resuscitative, diagnostic, and therapeutic measures for survival.

As a model for a trauma center, the Maryland Institute for Emergency Medicine (MIEM), formerly the Center for the Study of Shock and Trauma, is a self-sufficient unit. It occupies five floors: two floors are for patient care; one floor houses constantly staffed clini-

Dr. Schnaper is Chief, Psychiatric Branch, and Dr. Cowley is Director, Maryland Institute for Emergency Medicine, 22 South Greene St., Baltimore, Md. 21201. Dr. Schnaper is also Professor of Psychiatry and Dr. Cowley is also Professor of Cardiac and Thoracic Surgery, University of Maryland School of Medicine, Baltimore, Md.

The authors gratefully acknowledge the assistance of Andrea Reeves and Susan Baker.

cal laboratory and research facilities; one floor is devoted to hyperbaric oxygen therapy; and one floor is for administration. There are four clinical areas: the admission area, operating rooms, very intensive critical care, and step-down intensive care. Each area has its own basic nursing staff, and all areas interact with each other.

The MIEM functions as a systems control center for a statewide emergency medical service (10). Patient admission is immediate and without question from hospitals, referring physicians, and accident scenes. The patients usually have severe multiple injuries involving two or more systems and/or life-threatening illnesses resulting from overwhelming infections, suicide attempts, drownings, poisonings, ruptured aortic aneurysms, gastrointestinal hemorrhages, etc. More than 900 critically ill or injured patients are admitted to the MIEM each year. The survival rate is 80%, even though patients who are dead on arrival are considered live admissions for statistical purposes. Approximately 60% of the patients are brought directly to the MIEM from highway crashes by helicopter (11). These traumatized patients arrive suffering from varying degrees of shock and in varying levels of consciousness. A multidisciplinary, life-saving approach to the patient begins immediately at the heliport; treatment precedes diagnosis.

Within minutes of his or her arrival in the admitting area, the patient's clothes are cut away, six intravenous and intra-arterial lines are connected, intubation is performed, and laboratory and X-ray studies are made simultaneously. Intra-abdominal lavage rather than inspection and palpation is used to detect internal bleeding. Definitive surgery is performed when indicated. Comcomitant shock management is aggressive, with emphasis on adequate ventilation and volume replacement rather than dependence on pharmacological agents.

Once the patient's condition is stabilized, he or she is moved from the admitting area or operating room to a 12-bed critical care recovery unit, where he or she is intensively treated by ever-present doctors and nurses guided by electronic and laboratory monitoring. The intensive therapy begun in the admitting area continues. This includes medications, physical aids, and surgical techniques. Rehabilitation measures begin early as part of definitive care and continue through the reparative stage.

THE PATIENTS

The emotional responses of the patients seen in the trauma center include psychotic, neurotic, and behavioral reactions to the real or fantasied threats of their illnesses or injuries. The essence of the experience is stress. Even minor surgery can constitute a severe psychological threat to the patient. Any effort to understand these emotional responses must be predicated on an understanding of the fact that each person facing trauma brings to the encounter his or her own personality, which is used as a defense against the illness or injury and the factors that caused it (12).

Any threat, illness, surgery, or narcosis marshals coping mechanisms. The specific problems threatening the traumatized patient (2) include the following:

Helplessness. In any illness one becomes dependent on someone else for healing and comfort. The defense of regression follows dependency. The caretakers are viewed as protecting or parental figures. The more severe the physical injury, the more intense are the feelings of separation from family and abandonment. The amount of regression is proportionate to the severity of the injury and intensifies the patient's magical expectations of his or her helpers.

Humiliation. Injury and hospitalization also engender desperate feelings of indignity in reaction to hospital procedures, e.g., the bedpan, catheters, and taking blood. Severely traumatized patients are necessarily exposed to these procedures in the admission area and throughout their hospitalization. If they are unconscious when admitted, they experience this humiliation retrospectively when they wake up. If they are semiconscious when admitted, they might view their clothing being cut off and the other procedures as assault and battery—especially if they have been drinking alcohol.

Body image. One's body image is one's conscious and unconscious concept of the physical appearance of his body. Body image can also include one's car and clothing or one's perception of his environment, all of which contribute to a sense of identity (13). Emotional investment in a particular body organ is added to this, e.g., a woman's attitude toward the removal of a breast. In the severely traumatized patient, the threat of mutilation of his or her body is often overwhelming.

Mental symptoms. The traumatized patient may experience an altered state of consciousness due to either physical or emotional causes. Examples of physical causes are open-heart surgery, metastatic carcinoma, and massive asphyxia with resultant cerebral hypoxia. Emotional causes are usually based on a defensive dissociation to avoid an emotionally painful situation.

Patients Who Have Had Open-Heart Surgery

As indicated above, much of the literature has focused on the psychological sequelae to open-heart surgery. Other surgical procedures, such as plastic surgery, eye surgery, urological and gynecological surgery, cancer surgery, and organ transplants, precipitate psychiatric sequelae. Open-heart patients differ from trauma patients in that they have advance knowledge of what might happen to them. Trauma patients are struck suddenly, with only brief or no warning.

In spite of the fact that cardiotomy patients are more prepared than trauma patients, they often face emotional difficulties after the operation. The abundance of

articles on this subject (3, 14–22) testifies to the problem. Kornfeld and associates' review (17) is excellent. Baxter's survey (19) noted that postcardiotomy psychiatric symptoms are the most thoroughly studied of all postsurgical sequelae.

Freyhan and associates (16) studied 150 patients and found that 51% manifested psychiatric complications, a conservative estimate in view of the fact that some patients had "hidden" psychoses. Blacher (22) examined 12 "normal" cardiotomy patients and found that 4 had no overt psychosis and 8 had major symptoms. Just as syphilis can present pathologically as any medical entity, psychiatric symptoms after open-heart surgery can resemble any type of mental illness (16, 19).

Many factors contribute to the etiology of emotional disturbance after this kind of surgery. Often the cause is neurological illness and organic brain syndrome (16). We suggest that the patient brings to surgery a mild, perhaps undetectable deficit in brain oxygen caused by his or her illness. Such factors as more than 8 hours of anesthesia, more than 4 hours of bypass time, hypoxia, microembolic phenomena, membrane shifts, deleterious components in blood transfusions, the ICU atmosphere, sensory deprivation, and preoperative psychiatric disturbance contribute to psychological sequelae. The last factor gains implicit credence from the study by Kornfeld and associates (17) and Druss and Kornfeld (23): 38 of their 99 adult patients had a postoperative psychosis of the "acute organic variety"; none of the 20 children in the same study had a similar disturbance, however. (In contrast to study of the cardiotomy patient, there is no opportunity to evaluate the trauma patient preoperatively.)

Generally, the postcardiotomy psychiatric sequelae are in the form of a delirium state and are temporary. Preoperatively, neurotic reactions are exhibited by predisposed individuals who seem to be reaching for a longer life. Many, if not most, of these patients have suffered chronic physical ailments and have come to accept dependency as a way of life. Corrective surgery imposes a burden on them to relinquish this adjustment and to find new techniques for everyday living (12, 24).

An empirical observation at the MIEM is of interest: 8 patients with a ruptured abdominal aneurysm (4 survived) demonstrated over an 18-month period the onset and resolution of delirium in 3 to 5 days. In these cases there was no pump time and no prolonged anesthesia, but the postoperative psychiatric symptoms were similar to those seen after a cardiotomy. The assumption in both situations is that these patients had chronic ischemia before surgery and then received a hypoxic insult: the cardiotomy patients during surgery and the ruptured aneurysm patients before surgery, when blood loss was massive.

Patients with Head or Spinal Cord Injuries

Head and spinal cord injuries approximate multiple trauma. However, the literature, with one exception (1), is concerned with single system injury. Most of the writings have been oriented toward the posttraumatic syndrome or posttraumatic neurosis (25–34). Because head and spinal cord injuries often result in permanent emotional or physical disability, there is a pressing concern for rehabilitation in these cases (25, 32, 35, 36).

Head injury usually produces subjective symptoms. Headaches, fatigue, vasomotor lability, dizziness, poor concentration, irritability, personality changes, and vague somatic complaints comprise the usual pattern. The etiology of these sequelae is uncertain. Weinstein and Lyerly (37) suggested that unconsciousness for at least 8 hours might be a cause. Others (27, 32) have suggested that a history of alcoholism might predispose some patients to subdural hematomas. The most controversial etiological factor suggested is the possibility of financial compensation, which Miller (38) suggested might be a determinant of resistant symptoms.

It has been our experience that the real culprit is time. If rehabilitation of the patient with posttraumatic syndrome is undertaken within the first 6 months, the patient usually does well. If it is undertaken after 2 years, the rehabilitation potential falls to near zero. During this prolonged interval the patient becomes dependent on spouse or family for financial and emotional support. The male patient has the added problem of role reversal, and no amount of money can motivate him to "get up the nerve" to face the outside world. A similar pattern prevails in patients who have retired from work, particularly those who have not planned for retirement.

Spinal cord injuries can only be considered in the context of physical and emotional rehabilitation. Second cervical spinal transections are the most serious because the patient cannot survive without life support systems. These injuries evoke the most debate in the polemical area of euthanasia. Space limitations interdict our participation in this discussion.

In a perceptive paper, Bucy (39) offered some interesting statistics on paraplegics. Each year, 10,000 persons in the United States (50 per 1 million) become paraplegics. Eighty-five percent are men 18 to 25 years of age, and 50% of these cases result from auto accidents; the remainder result from other accidents, predominantly those involving sports.

According to Mueller (35), the emotional problems of paraplegic patients stem from the role reversal from independent to dependent. The initial reaction is depression, despair, bitterness, and grief. How well the patient adjusts depends on his or her personality assets or liabilities. Some preoccupy themselves with frustration, autistic thinking, and dependency as they relate to their damaged body image. Others, with family support and an acceptance of their physical limitations, seek a new role in life. They are motivated to set goals and accomplish social, economic, and vocational objectives.

The body image problems of paraplegics are differ-

ent from those of amputees. The latter experience phantom limb sensations. Paraplegics' efforts at denial are difficult because they can see their extremities. They also have to adjust to other physical disabilities: root pain can be severe, bladder and bowel control may require many surgical procedures, and sexual capability can be an overriding concern; however, the latter can be alleviated by physical and plastic aids and ingenuity.

Multiple Trauma Patients

Severely traumatized patients are usually products of automobile accidents, shootings, stabbings, falls, etc., and are generally in shock, unconscious, and near death. Unlike cardiotomy patients they are unprepared for the experience.

The core experience for trauma patients is unconsciousness. After 3 to 15 days in this state, they attempt to fill the void in consciousness retrospectively. Of 68 patients interviewed after gaining consciousness at the MIEM, 43 were amnesic, 8 were initially amnesic but subsequently recalled their experiences, and 17 recalled the experience without difficulty. The latter two groups used fantasies and distortions in their recall (2).

Many traumatized patients are amnesic, but some, if given enough time and fed bits of information by relatives, report dreams they had while in the unit. An almost universal theme of these fantasies is being held prisoner. The reason for being incarcerated is highly individualistic and predicated on the particular patient's psychological development. Of 25 patients interviewed at the MIEM, 22 recalled feeling that they were being held prisoner. Fourteen of these patients recalled feeling that they were trying to escape.

Interwoven, and perhaps interrelated, with the fantasies of imprisonment is the patient's feeling a very real death-like experience. At times there is a conviction that one is dead; at other times there is doubt as to whether one is dead or alive. Some patients report both experiences. Others, feeling the uncertainty, encounter and observe death. Of 25 patients interviewed at the MIEM, 18 recalled feeling that they were dead. Fifteen of these patients recalled feeling that they were "just nothing," and 3 recalled not being sure whether they were dead or alive. It is interesting that none of the 25 patients expressed feelings about dying. The 18 patients who reported a death-like experience referred only to the state of death.

One can readily identify with the patients in this position. They are incarcerated in a featureless cubicle and have no contact with the normal world. There are no windows, no pictures, no flowers—just masked, hatted, uniformed wardens who usually hurt. The patients are deprived of sleep (if they are conscious) by 24-hour monitoring, the hiss of a respirator, and background noises. Their transfer by helicopter makes its own realistic contribution to the patients' sense of physical disorientation.

Disorientation and depression occur frequently on the unit. The staff members are alert to these sequelae and respond appropriately and quickly. Such personal items as photographs and tape recorders are provided, as well as verbal reassurance.

Two pertinent issues merit discussion. One is the differentiation of postoperative delirium from postoperative psychosis, and the other is the differences between the typical ICU patient and the typical trauma center patient.

Classical delirium demands an investigation of organic causes, but functional psychosis requires watchful waiting and proper supportive measures. Psychosis is usually resolved in 48 to 72 hours (40) and can be established by ruling out organicity and by finding out if the patient has a history of predisposition to psychosis. Disorientation and visual hallucinations suggest a metabolic disturbance and toxicity.

Although both psychosis and delirium may be evident in the ICU and the trauma center, the patients in these two kinds of facilities differ. The patients in the ICU are prepared; the trauma patients, as a rule, are not. The trauma center patients are usually unconscious when they are admitted, and their unconsciousness may be prolonged; they awaken to total confusion.

Not only are trauma patients unprepared, but they must account retrospectively for the void in their consciousness. One of the 22 patients at the MIEM who recalled feeling imprisoned felt that he was being held prisoner because he had killed a schoolbusful of children with his heavy truck (his injury occurred when he was crushed between the body and the cab of his truck while parked) and because he believed that he had urinated in bed. He observed his death by seeing his name on a tombstone. Another patient, a widow who had been injured when she drove her car over an embankment, felt that she was being held to be sold into white slavery.

The crucial dynamic in both cardiotomy patients and traumatized patients is a system of defenses. The cardiotomy patients have mobilized their defenses; the trauma patients have not. With the return of awareness, the trauma patients' defenses are intensely mobilized as the patients seek an explanation for the void in their consciousness. Although this is usually a homeostatic effort, it evokes painful images of death and fantasies of "badness" as reasons for incarceration. These unrestrained beliefs are the products of severe psychological regression accompanying the injury. Emotionally, the patient is a child in a punitive situation that he or she deserves.

THE STAFF

The staff are the "heart and soul" of the ICU and the trauma center. Collins and Ballinger (4) stated that "people more than anything else determine its value."

In a trauma center there are many emotional compensations for the staff in the affectively intense and

critical caretaking. The staff carry great responsibilities and can thereby gratify their omnipotent fantasies. They also encounter great stresses, frequently compounded by fatigue. In addition there are different transference and countertransference attitudes among the physicians, nurses, and ancillary personnel.

Physicians

The recent emphasis on the study of the total person and the recent increase in specialization have had a curious impact on patients. As a byproduct of this paradox, patients are cared for by scientists rather than family doctors (12). The trauma team aims at combining various medical and surgical specialties to treat the patients' multiple injuries and their psyches—to treat the total person.

The physician's sense of omnipotence is a double-edged sword. It spurs him or her to work long hours, far beyond the call of duty. Saving the patient's life is paramount. When physicians succeed, they radiate charm and good humor. On the other hand, when their omnipotence fails, they can be irritable or, after a long, hard battle to save a patient, shed tears for themselves as well as the patient. There are some physicians who experience a patient's death as an attack on their training, competence, person, and the integrity of their fantasies of being godlike (41).

Hay and Oken (9) reported the reaction of physicians in an ICU when a patient was failing. They became very authoritative with the nurses, demanding that they be waited on. Also, they either disappeared or tried all sorts of vain heroic measures.

The emotional tensions of the work predispose physicians in trauma centers to peaks and lows in relationships with their coworkers. Dedication to the task of saving lives, however, supersedes transient human frailties. The test of the physician rests in the quantity and quality of the lives saved.

Nurses

In the trauma center nurses are an integral part of the decision-making process and are involved in the crucial aspects of the patient's care. They may be required to act without hesitation, often on the basis of their knowledge and experience alone. Diagnosis becomes an important part of their job if they are to initiate treatment with the split-second timing necessary to save a life. The emphasis is on coordination, planning, and patient assessment so that crises can be avoided. The nurses' responsibilities can be overwhelming or gratifying, irritating or satisfying.

Our observations coincide with many of those of Hay and Oken (9). For the nurse, the ICU and the trauma unit are inherently stressful environments: the machines (they must also be mechanics), the constant stimuli, and the overload of patients, some of whom are bloody, incontinent, and/or dying. Coping requires some degree of defensive detachment (3). The routine can be repetitive, and patients' relatives are always around. The nursing administrative staff are not always aware of the demands made on nurses in the trauma unit.

Bilodeau (42) and Kellogg and Curran (43) came to similar conclusions: that the sources of satisfaction are also the sources of dissatisfaction. The sources of stress fall into the categories of patients and patient care, peer personnel, physicians, the environment, families, personal difficulties, and conflicts with other areas of the hospital. Frustration is manifested by fatigue, forgetfulness, depression, and guilt. The defenses used against these problems are denial, displacement, projection, repression, reaction formation, and passive aggression.

There are compensations in the esprit de corps of the trauma center staff in spite of occasional lapses in cooperation. Although not condoned, mistakes can be forgiven. The overall feeling of the staff is one of elitism, a fact not borne very gracefully by such "outsiders" as the general hospital nurses.

The trauma center nurses, without exception, are psychiatrically oriented. At times they are too much so; there is a tendency toward overidentification with the patient and/or his or her family. Occasionally what seems to be a paradox occurs: when aggressive therapy is discontinued (with the family's awareness), one or several nurses will complain about the physician giving the order; on another day, the same nurse or nurses will be critical of a physician for not terminating aggressive therapy with another patient. Situations like these are handled in group meetings, discussions with supervisors, psychiatric consultation, reading, courses, and seminars. Good physician-nurse communication is essential to the trauma unit.

Unlike other physicians and nurses, those in a trauma center must wait until patients regain consciousness to establish a relationship with them. The physicians as well as the nurses must develop skill in communicating with tracheostomized patients who cannot talk and who may be delirious. They must anticipate, sense, and read the patients' eyes, gestures, and body language. At all times, they must also be available to reassure the patients' families, either in person or by telephone.

THE ROLE OF THE PSYCHIATRIC CONSULTANT

Lipowski (44) discussed the history, scope, aims, organization, and functions of the psychiatric consultant. He stated that the consultant acts as a "mediator and bridge builder" between the medical-biological and psychiatric-behavioral disciplines. He emphasized that a consultation service should be staffed by full- and part-time psychiatrists, liaison nurses, social workers, and psychologists. He also stated that "a consultant is invariably a therapist."

The University of Maryland Department of Psychiatry provides a liaison service to other areas of the university's general hospital. The MIEM has this service incorporated into its organization. We have a chief of

the psychiatric branch, a family services branch, social workers, psychiatric nurses, and a resident who rotates from the liaison service of the department of psychiatry.

That psychiatric referral from other disciplines is accomplished with reluctance is a fact of medical life. Territoriality strives to "protect" patients from psychiatric intervention (45). However, it has been our experience that the psychiatrist's personal willingness to be involved and available increases his or her use as a consultant. As time goes on, he or she becomes friend, counselor, partner, and troubleshooter. In a trauma center psychiatric consultants are like circuit riders. They are on the scene, taking their services to the consumer—quite the opposite of working in one's office. The psychiatrist does not "visit" the unit, he or she "lives" there.

In a unit as intense as the MIEM, which has a large number of personnel and a psychiatric consultant available, curbstone consultations are inevitable. The personal problems of the staff become the confidential province of the consultant, who deals with such problems as referrals for psychotherapy to psychiatrists who are not connected with the unit, depression, psychosis (rarely), suicide attempts (rarely), abortion counseling, family decisions, and problems with boyfriends or girlfriends.

Koumans (46) described the dividends for the psychiatrist on an ICU: appreciation and communication between medical and psychiatric staffs and better use of the consultant's time and skills. After more than 3 years of experience with this concept in a trauma center, we would add that there are other personal satisfactions. The MIEM is unique; the diversity of acute medical and surgical problems we handle gives the psychiatric consultant a perspective of people and health care that he or she could not get in an office or in a single-specialty ICU. The psychiatrist "living with" the unit develops a gratifying sense of belonging as a team member. (On the other hand, he or she may occasionally be viewed simply as a medical colleague; other staff members forget that he or she is also a psychiatrist.)

DISCUSSION

War brings with it sudden, overwhelming numbers of casualties. The same applies to epidemics and such physical disasters as earthquakes and airplane crashes. The trauma center, of which the MIEM is a unique example, is the proving ground for the competent management of these emergencies.

We think it is important that accidents are the leading cause of death in people between the ages of 1 and 37 in the United States (47). Hirschfeld and Behan (48) stated that accidents "are events which are captured by the personality for the purpose of solving the individual's life problems." Reflecting a similar attitude, Rome (49) stated,

> Very little in nature is truly capricious, deserving of the designation "accident." For the most part, our use of the term actually means that the antecedents of the event have not been analyzed in sufficient detail to establish the logical, scientific basis required for a suitably parsimonious explanation of its pathogenesis.

In *Accident or Suicide?* (50), drinking rather than a desire for self-destruction was incriminated as a cause of accidents. Three groups were compared: 25 accident cases, 29 completed suicides, and 31 completed appendectomies. There was little difference between the accident patients and the appendectomy patients as to self-destructive tendencies. Our empirical observations at the MIEM leave some doubt as to the validity of this study, however. One-third of the 25 accident patients were amnesic, but 43 of the 68 patients we interviewed at the MIEM (well over half of the patients) were amnesic (2). Perhaps further research can confirm or dispute their findings.

Other investigators have concerned themselves with the question of self-destructiveness as it relates to accidents. Crancer and Quiring (51) compared the driving records of 915 persons hospitalized for suicidal gestures with those of 687,228 drivers in Washington State. The suicidal gesture group had an 81% higher accident rate, a 14% higher violation rate, and had had significantly more violations for accidents resulting in injury, for drunk driving, and for negligent driving. Selzer and Payne (52) conducted a similar study and came up with similar findings: patients with self-destructive tendencies had twice as many automobile accidents as those without these tendencies.

The combination of drinking alcohol and a tendency to self-destructiveness also contributes to the possibility of accidents. Hämäläinen (53) concluded on the basis of a study of one-car accidents that there is "a certain link between auto accidents and self-destructive trends in Finland." One can readily assume that the combination of alcohol consumption and driving is injudicious and a reflection of self-destructiveness.

A particularly fascinating area of research is the problem of amnesia. Very little has been done on this subject since Weinstein and associates (1) studied amnesia as a language pattern in 1962.

Weisz and Boyd (54), who reported on a trauma center in an "underprivileged" urban area, pointed out a tendency for a high incidence of trauma in certain communities. They described a pre-trauma sociopathic personality-trauma-enhanced sociopathic behavior interrelationship. They concluded that a study of the epidemiology of trauma in socioeconomically deprived areas would be useful.

Beyond the physical management of trauma there is an urgent need for psychological investigation. Some of the questions that need answers to complement the work of the traumatologist are, What was going on emotionally within the patient before his or her accident? Was there an unconscious wish for suicide? Did the victim unconsciously structure the "accident"? Does the alcoholic state mask something else? Are the

fantasies of death and imprisonment derived from real or fancied guilt for the accident? What significance do the organically induced alterations in levels of consciousness have in psychological defensive operations?

PATIENT MANAGEMENT

Management of the traumatized patient begins with preventing complications, if possible. Braceland (15) suggested that cardiac surgery patients be told what to expect, that a clock and/or a calendar be placed in the ICU, that the patient be removed to a private room as soon as possible, and that the staff not get strung out. Others (19, 46, 55, 56) have recommended that visitors be allowed but restrained when necessary, that the ICU environment be softened, and that a psychiatrist be on the staff.

The presence of multiple trauma requires immediate and aggressive therapy. When time is of the essence, one cannot be mindful of the humiliation a patient might feel when his or her clothes are being cut away. Once the patient is stabilized there is time to be aware of the patient as a person who is feeling threatened and has mobilized his defenses. This is not to imply, however, that the trauma team neglects a humane concern for the patient.

Some suggestions arise in interviews with patients about their experiences. When patients are unconscious (or seem to be, as with stroke), they need to be spoken to, called by name, touched, and handled as gently as possible. Obviously, prognostications at the bedside should be avoided. The patient who starts to detail "crazy ideas" needs reassurance, verbal support, and appropriate medication.

CONCLUSIONS

The day may not be too far off when surgery, at least in the Western world, will be limited to trauma, transplantation, congenital defect, and cosmetic repair. It behooves the psychiatrist to be alert to this possibility because his or her insights will be needed. In the trauma center as in the ICU, crisis is a way of life. The role and the obligation of the psychiatrist of the future will lie in crisis intervention within the medical-biological model. The team concept, with its multidisciplinary approach, ensures that the patient will receive intensive treatment according to the highest standards of the practice of medicine.

Effects of Peer Review on Outpatient Psychotherapy: Therapist and Patient Follow-Up Survey

BY LORRAINE L. LUFT, M.C.P., LAWRENCE M. SAMPSON, M.D., AND DONALD E. NEWMAN, M.D.

Interviews with 80 therapists and 50 patients at a community mental health center revealed that peer review effectively monitored the appropriateness of treatment and allocated limited treatment funds without unduly interfering with established treatment patterns, relationships, or outcomes. Most therapists reported receiving helpful consultation from the peer review committee, and the process encouraged them to focus more clearly on treatment goals. On the other hand, patients were concerned about the committee's role in making decisions about their treatment. Therapists noted as a problem the lack of certainty in establishing a treatment contract prior to peer review since the contract with the patient must remain fluid during the evaluation period. The therapists and patients demonstrated remarkable agreement in their assessment of treatment progress and whether further therapy was needed.

THIS PAPER REPORTS on the effects of a peer review system on psychotherapeutic relationships and outcomes from the perspective of both therapists and patients. The study was conducted at Peninsula Hospital Community Mental Health Center in Burlingame, Calif. This mental health center, which opened in 1969, serves approximately 2,500 people per year from its catchment area of 95,000 and has developed a comprehensive array of both direct and indirect services. The center operates on a private practice model, with all of the therapy provided by privately practicing psychiatrists, psychologists, and social workers in the 80-member department of psychiatry.[1]

Combined version of two papers presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are with Peninsula Hospital Community Mental Health Center, 1783 El Camino Real, Burlingame, Calif. 94010, where Ms. Luft is Director of Program Evaluation, Dr. Sampson is Co-Director of Adult Inpatient and Partial Care Services, and Dr. Newman is Director of the Center.

This work was supported by Alcohol, Drug Abuse, and Mental Health Administration contract 42-74-91 from the National Institute of Mental Health.

The authors wish to acknowledge the collaboration of Vard Kazanjian, Ph.D., a member of the hospital's professional staff, and Pamela A. Mc Mickin, M.A., Program Evaluation Assistant at Peninsula Hospital Community Mental Health Center.

[1]For a fuller description of this model of service delivery, see reference 1.

Approximately 60% of the patients seeking help at the center are eligible for state and county funds, which are provided to subsidize the cost of treatment for those patients who cannot afford the full cost of care but are ineligible for Medicaid. While the mental health center has a contract with San Mateo County to provide treatment to this group of patients within the catchment area, there is a limited budget with which to do this.

After a year's experience with the fee-for-service private practice model and laissez-faire spending for treatment, it became obvious that a system was needed to more judiciously allocate the center's budgeted state and local funds. In order to meet this need, the department of psychiatry and the center established a peer review committee in March 1971 and specified that outpatient cases must be reviewed after 6 visits with the therapist. Since the inception of this peer review system, there have been approximately 2,000 outpatient case reviews.

The architects of this peer review system felt that since the reviewers would be under pressure to shorten treatment recommendations, the committees should be composed of clinicians oriented toward long-term treatment in order to achieve a balance; this tradition has persisted. Three therapists serve on each review committee: two are attending therapists from the department of psychiatry who are paid a clinical fee for their review time; the third reviewer is a member of the salaried clinical staff of the center. Therapists present their cases at weekly meetings, and the committees and therapists jointly work out a proposed plan of treatment linked to explicit treatment goals. While the committees exercise full control in authorizing the use of services and, therefore, the allocation of the budgeted community funds, the atmosphere of the meetings is more akin to that of a clinical case conference than an administrative review. The overriding goal is to maintain the delicate balance between clinical needs and fiscal realities.[2]

When the negotiation of the treatment plan was changed from the sole control of the therapist and patient to include the peer review committee, there were many concerns about the impact of such a system on the patient-therapist relationship and the course of treatment. Clearly, the introduction of any third party into the treatment relationship has a poten-

[2]For a more complete discussion of the format and functioning of this peer review system, see reference 2.

tial for significantly altering that relationship, with possible effects on the outcome of therapy. Since the third party in this case was a committee of peers, with whom the therapists had professional and often social contacts, and which was empowered to make decisions about modalities, frequency, and duration of treatment, the potential for impact upon therapy seemed very great and led to this study.

Interviews were conducted with all of the 80 attending therapists regarding their general reactions to peer review. In addition, the 60 therapists who had treated 1 or more terminated patients whose cases had been reviewed were asked questions about the impact of peer review on selected cases. The interviews were conducted in the therapists' private offices with full assurance that the material would be considered confidential. The interviewers were graduate students in psychology who were hired specifically for this project. Of the 103 patients in our sample, 60% were treated by psychiatrists, 17% by psychologists, and 23% by social workers. Fifty of these 103 patients were interviewed regarding their treatment, and their responses were compared with those of their therapists regarding the impact of peer review on the entry into treatment and the adequacy of treatment provided.

IMPACT OF PEER REVIEW ON ENTRY INTO TREATMENT

Only 31% of the therapists said they would be less inclined to accept a patient whose case required review than they would a private patient. It is interesting that 35% of the psychiatrists expressed this reluctance, compared with 50% of the psychologists and only 11% of the social workers. An additional way of avoiding peer review is to terminate the patient before the time for review. However, the proportion of patients who terminate in 6 sessions or less has decreased from over 40% before the implementation of peer review to 24% during the last fiscal year.

The therapists reported that the peer review requirement affected their history taking in about one-third of the cases. Their primary comment was that they felt under pressure to obtain a more detailed case history for presentation to the committee and therefore more actively questioned the patients, rather than letting them reveal the material at their own pace. Similarly, one-third said that peer review affected how they set treatment goals; they often commented that they had to think in terms of more time-limited, concrete goals instead of letting the patient set the pace. A number of respondents commented that knowing they would present the case led them to think more distinctly about treatment goals. Approximately one-fifth reported that they kept more thorough notes on patients to be presented to peer review, and 10% said that peer review had some effect on their specification of a diagnosis.

In general, the findings indicate that peer review did not affect treatment as much as many had anticipated. It is apparent that peer review had its largest impact on preparing the patients for treatment; this factor was mentioned in half the cases. Not surprisingly, the therapists generally commented that they had to leave the treatment contract open and inform the patient that continuing treatment would depend on the committee's decision.

PATIENTS' REACTIONS TO PEER REVIEW

There were substantial differences in the way that patients and therapists described the process of establishing a treatment contract. In almost one-fourth of the cases, therapists and patients disagreed about whether they had discussed the matter of the peer review committee. In only 3 of the 50 cases (6%) did the therapists state that they did not tell the patient about the peer review process, and in 3 other cases (6%) they could not remember. In 42 of the cases (84%) they said that they told the patient before the peer review presentation, usually during the first visit. There was considerable variation in what was said, however, with some therapists describing the process at length while others only mentioned it briefly. Some described it to the patients as a case review and others, as a financial discussion. One therapist told his patient that the decision about treatment was completely up to the committee.

It is interesting that 12 of the patients (24%) stated that they were not told about peer review and 2 others (4%) could not remember being told. Only 1 therapist and 1 patient agreed that the issue had not been discussed; of 12 patients who claimed they were not told about the committee, the therapists claimed that they told 10 of them. This difference is quite striking and is reminiscent of other issues about which patients often claim they were not told, such as being charged for missed appointments or therapists' vacation plans. On the other hand, some therapists might not have recalled the omission or were too embarrassed to admit that they had neglected or glossed over such an important issue in the therapy.

One-third of the patients did not like the idea of their therapist discussing their treatment with a committee, one-third said it did not matter, and one-third said that it was fine with them. Those who felt negatively about it were concerned primarily about the issue of confidentiality and resented anyone other than their therapist making decisions about their care. They were concerned that the therapist might not adequately portray their needs to the committee, and many feared that the committee would set a higher fee than the therapist had set. Those who claimed indifference to the committee generally explained that this was the price one paid for low-fee, publicly supported therapy. Of those who felt positively about it, many said that they could benefit from the committee members' experience and recommendations. The patients made similar re-

sponses when they were asked about the committee's power to make decisions about their cases.

IMPACT OF PEER REVIEW ON TREATMENT RELATIONSHIPS

The therapists felt that peer review had no effect on the establishment of a therapeutic alliance with three-fourths of their patients. Of the 25% who said that it had an effect, approximately two-thirds, or 20% of the total, felt that it interfered, while one-third, or 10% of the total, reported that it improved the establishment of a therapeutic alliance. Those who felt it interfered generally commented that they were initially less involved, tried to minimize any transference, and did not want to open up certain areas with the patient if they would not be able to continue the therapy. One therapist commented that he scheduled a second review of a case since he felt angry and was dissatisfied with the committee's recommendation. He felt that the patient sensed his confusion and it disrupted the alliance. On the other hand, one patient who worked in a bureaucratic situation felt that the therapist better understood bureaucracies and was more of an ally after participating in peer review as her advocate.

The therapists felt that their patients' resistance to treatment was increased by the peer review process in slightly more than one-fourth of the cases. One therapist stated that his patient, who was highly resistant to looking at herself, was able to focus her concerns on the committee's impending decision and thereby bolster her attempts to deny her problems. Another therapist stated that her patient misunderstood their early discussion about the committee and missed the sixth appointment, saying, "If 6 sessions is all we have, don't offer me anything." In another case, the therapist noted that the patient was very reserved until the committee decision was made; she then allowed herself to become close to the therapist.

On the whole, however, both the therapists and patients agreed that the review requirement did not interfere with their treatment relationships. Of 34 patients who knew about peer review, only 18% felt that the committee interfered with their relationship with their therapist, and several of these patients said that they consciously withheld information about themselves until the committee had met and decided on the treatment plan. Only 9% of the patients indicated that their feelings about their therapists changed because of the requirement to present the case, but many respondents gave brief and guarded responses about this issue. The therapists felt that the peer review requirement had no effect on their professional image with most of their patients. They felt that their image was eroded in 16% of the cases, while in 10% they felt that it was enhanced. About two-thirds of the patients and therapists agreed that peer review did not have a negative effect on the therapeutic relationship. In half of the remaining cases only the therapists felt that it interfered, and in the other half only the patients felt that it interfered. In only one instance did both patient and therapist agree that peer review interfered with their relationship.

Thus the most significant initial effects of the peer review requirement were in preparing the patients for treatment, gathering the histories, and setting goals for treatment.

PEER REVIEW PRESENTATION

In presenting the majority of the cases to the peer review committee, the therapists reported that they felt that they served as an advocate to obtain the necessary resources for the patient and that they also received consultation from the committee.[3] It is interesting that while three-fourths of the therapists felt that they received consultation, 80% reported that the review had no effect on their evaluation of the patient. This is consistent with frequent comments that the consultation confirmed their own clinical impressions. Virtually all of the therapists whose evaluations were altered by the review felt that the review was helpful. Typically, the review was helpful in setting realistic expectations for the patient and exploring countertransference issues.

In two-thirds of the cases, the therapists reported that the committee's decision was consonant with their own treatment plan. In the context of this positive finding, however, several therapists remarked that they had already scaled down their requests since they were aware of the fiscal constraints. It is thus difficult to know precisely how much the presenting therapists internalized the function of the committee and reduced their requests to conform to their perception of what the committee would approve. In one-third of the total cases, the committee recommended changes in the therapists' original treatment plans. The most frequently recommended change called for a reduction in the length of treatment (22% of all cases). Other alterations in treatment plans included changes in modality (13%), approach (12%), and frequency of sessions (13%). (These percentages total more than one-third since in some cases the committee recommended more than one change.)

OUTCOME AND ADEQUACY OF TREATMENT PROVIDED

In evaluating the results of therapy, the agreement between patients and their therapists was quite remarkable ($\chi^2 = 17.01$, $p = .002$). In both groups, an average of 77% felt that the patient improved, about 18% felt that he remained the same, and about 5% felt that he got worse. Of the 37 patients who felt that they improved,

[3]For a discussion of the educational potential of peer review, see Newman and Luft (3).

their therapists thought that 32 of them improved and 5 of them remained the same. Of the 4 patients who felt they got worse, their therapists thought that 1 was worse, 1 better, and 2 were the same. Of the 8 patients who felt they remained the same, their therapists felt that 3 were the same and 5 were better.

The patients and therapists also agreed to a significant extent about who needed more therapy and who did not, with total agreement in two-thirds of the cases ($\chi^3=6.47$, $p=.04$). Of the 22 patients who felt that they needed more therapy, their therapists felt that only 6 of them had had an adequate amount of treatment. Similarly, of 20 patients who felt that they had had an adequate amount of treatment, their therapists observed that only 5 of them should have had more therapy. The therapists felt that 44% of their patients should have had more treatment, that 30% had adequate time approved, and that 26% had other extenuating circumstances that generally led to the patient's termination. One-third of the patients in this sample later returned to the therapist or entered treatment elsewhere, with 20% becoming privately paying patients continuing with the same therapists.

Although the therapists felt that only about 30% of the patients had had an adequate amount of time in therapy, almost 60% of the patients did not use all of the time allotted to them by the peer review committee. In 75% of the cases up to 32 hours of treatment were approved; but the maximum time used was 16 hours. The median time approved was 15 hours, while the median time used was 8 hours. These median figures are similar to those reported by Langsley and Lebaron (4) in their survey of 97 private-practice psychiatrists in the Central California Psychiatric Society, which showed a median number of office visits from 8 to 13 for patients in different diagnostic categories. Not surprisingly, the range reported in that survey was far greater, with as many as 390 visits reported for patients in some diagnostic categories, while the maximum time approved by the Peninsula Hospital peer review system was 104 hours in this study.

For both therapists and patients chi-square analysis revealed no significant relationship between duration of treatment and improvement. Similarly, for both groups there was no significant relationship between duration of treatment and the need for more treatment. Thus it appears that one cannot predict how much more therapy patients may need by reviewing how much treatment they have already had; such decisions must be made on an individual basis.

Most of the members of the department of psychiatry preferred insight-oriented individual psychotherapy; yet in this patient sample they listed it as the primary treatment modality for only one-fourth of the patients. (See table 1 for a breakdown of the treatment modalities used.) We asked the therapists whether the patients would have been in longer-term insight-oriented therapy were it not for the limitation of funds and peer review. However, they responded that this would be appropriate in only 30% of the cases and that it might possibly work in an additional 5%. Thus it appears that while most of the patients were not in insight-oriented treatment, the reasons for this were not due to peer review or financial limitations; rather, the therapists felt that these patients were not able or motivated to use this form of therapy.

TABLE 1
Treatment Modalities Used with 103 Cases Examined by the Peer Review Committee

Treatment Modality	Cases	
	Number	Percent
Supportive treatment	29	28
Insight-oriented individual psychotherapy	26	25
Several modes	15	15
Evaluation	10	10
Group therapy	8	8
Crisis intervention	7	7
Reality therapy	5	5
Marriage counseling	3	3

Thus we can conclude that although most of the patients did not use the total time allotted to them by peer review and both therapists and patients felt that the patients often should have had more treatment, they nonetheless agreed and were quite positive in their assessment of the effectiveness of the treatment provided. Furthermore, most of the dissatisfaction with the length and modality of treatment was attributable to factors other than peer review.

Finally, we hypothesized that the therapists' participation in peer review would have an effect on their treatment of nonreviewed patients, but this turned out to be minimal. None of the therapists said that it affected the types of patients they saw, and only about 10% said that it influenced the modalities they used or the length of treatment for their other patients. The most significant response was in terms of setting goals for treatment. Overall, one-fourth of the therapists who had presented more than 10 cases to the committee said they now thought more concretely and systematically about treatment goals for all of their patients.

SUMMARY AND CONCLUSIONS

The impact of peer review on the treatment process was not as disruptive as many had feared and in fact was deemed helpful in certain situations. Peer review appears to help the therapists focus more clearly and concretely on the establishment of treatment goals, and for those who present frequently to peer review, this carries over to their non-peer-review practice as well. On the other hand, one of the problems that presenting therapists frequently note is that, with third-party involvement in the formulation of a treatment plan, the contract with the patient must remain fluid

during the 6-session evaluation period. In some cases this lack of certainty at the interface between evaluation and treatment is a problem, which at times actually leads to no treatment contract being made.

There were considerable differences in how therapists explained peer review to their patients, and one-fourth of the patients reported that their therapists never told them about it. Patients' reactions to the committee's role were mixed: one-third stated they did not like others making decisions about their therapy and were concerned about confidentiality; one-third said they were indifferent to the committee; and one-third thought they could benefit from the professional expertise of the committee. Overall, however, only a small percentage of the therapists and patients felt that the peer review committee interfered with the establishment of a therapeutic alliance and with therapeutic progress. Three-fourths of those presenting cases felt that they received consultation from the committee, and this consultation often confirmed their diagnosis and treatment plans and at times helped resolve difficulties and issues of transference and countertransference.

While our primary concern was overutilization, with peer review the patients used less than three-fourths of their authorized treatment time, and this allotted time was often felt to be minimal by the review committee. Furthermore, these data show that patients and therapists demonstrated remarkable agreement in their determination of when therapy was adequate and when more treatment was needed. Some patients did quite well with 6 visits, whereas others were felt to need more treatment after 100 visits. It is clear that treatment needs are an individual matter, and systems that attempt to fix treatment duration according to diagnosis or symptoms cannot help but miss the subtleties that can be evaluated in a case conference or by the therapist and patient together. It appears that in the system studied, the peer review committee effectively monitored the appropriateness of treatment and allocated limited treatment funds without unduly interfering with established treatment patterns, processes, or outcomes.

Behavior Therapy and Sex Therapy

BY JOHN PAUL BRADY, M.D.

Behavior therapy is characterized by the way in which clinical data are collected, analyzed, and used in the treatment program–specifically, the application of the methods of experimental and social psychology. A case history of the behavioral treatment of a sexual problem is presented to illustrate this process. Many people have assumed that the "new sex therapy" is behavior therapy because of its focus on the here and now and similarities in particular treatment maneuvers. However, the author notes that sex therapy is behavior therapy only to the extent that it deals comprehensively with environmental, interpersonal, and organismic factors that operate to maintain the sexual problem.

THE TERM "sex therapy" has come to mean highly directive approaches to the treatment of sexual dysfunction in individuals or couples. In these approaches, focus is on manifest sexual problems and interactions in the here and now. The bold and innovative approaches developed by Masters and Johnson (1) and further elaborated by Kaplan (2) and others clearly indicate that many sexual problems can be substantially improved without lengthy, insight-oriented, psychodynamic psychotherapy, i.e., without involving presumed unconscious and unresolved conflicts and deep-seated personality disorders. Because of this focus on manifest behavior, many clinicians have stated or implied that the "new sex therapy" is really behavior therapy for sexual problems. Indeed it is true that some of the therapeutic manipulations of a behavior therapist in the treatment of a particular patient may resemble those employed by a sex therapist in a similar clinical situation. This similarity is often more apparent than real, however. A fundamental difference is seen when we examine the behavior therapist's total approach to the patient. In this paper I will try to elucidate this difference by describing the essential, distinguishing features of a behavioral approach and presenting a case history illustrating this approach in the psychiatric treatment of a case of sexual dysfunction.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Brady is Professor and Chairman, Department of Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, Pa. 19104, and Research Scientist, Eastern Pennsylvania Psychiatric Institute, Philadelphia, Pa.

Behavior therapy or behavior modification is an approach to clinical problems that makes extensive use of the findings of empirical behavioral science. Particular use is made of the body of knowledge developed by experimental psychologists and known as principles of learning or learning theory, which describes the lawful relationships between the behavior of an organism and its physical and social environment. However, more central to a behavioral approach than any particular set of experimental findings is the use of methods of experimental and social psychology, specifically, the use of methods of procedure and rules of evidence termed "methodologic behaviorism." These have been succinctly summarized by Mahoney (3) and include an assumption of determinism (systematic relationships characterize certain classes of events), the use of operational definitions of variables, an emphasis on controlled experimentation and the independent replicability of observations and results, and the falsifiability (testability) of hypotheses.

The behavior therapist uses a similar strategy in his approach to clinical problems. By a combination of a detailed history and direct observation, he seeks to relate the various problematic behaviors (symptoms) of the patient to other identifiable events of a physiological, behavioral, or environmental nature. Such an analysis leads to clinical hypotheses about the "meaning" of the patient's symptoms—not in any philosophical or final sense but in the natural science sense of functional relationships among observable variables. A program of behavioral treatment consists largely of testing these clinical hypotheses, often by manipulating behavioral and environmental variables thought to be functionally related to the patient's difficulties. Thus the distinguishing characteristic of behavior therapy is the manner in which clinical data are collected and analyzed and then made use of in the design of the treatment program (4, 5). I will describe the behavioral treatment of a patient with a sexual problem to illustrate this process.

CASE REPORT

Mr. G was a 27-year-old married attorney who was referred because of intermittent impotence. He had been medically evaluated by his internist and a urologist some weeks earlier and no physical basis for the sexual dysfunction was found. The behavioral assessment of the clinical problem included interviews with

Mrs. G alone and with her husband in order to corroborate his account of the difficulty and to adequately assess the marital relationship in general.

The couple had been married 2 years earlier after a courtship of several years. Mr. G is a devout Catholic who had no coital experience prior to the marriage. Impotence was an occasional problem after a few months of marriage but only began to concern Mr. and Mrs. G greatly 6 months before they entered treatment. The patient's adjustment at work, in the community, and with friends seemed adequate, but he reported increasing tension and disagreements with his wife, particularly around the issue of his sexual limitations. He reported no other psychiatric symptoms aside from occasional excessive intake of alcohol.

Mrs. G was 29 years old, appeared more self-assured than her husband, and reported some coital experience with other men some years before their marriage. She usually had an orgasm in coitus with her husband if he maintained an erection long enough.

The couple agreed that impotence had become a frequent and major problem to them and their marriage since a particularly disturbing incident 6 months earlier during a skiing trip. They had hoped to spend a relaxing weekend alone together, but the patient drank excessively on both evenings and was unable to perform sexually afterward; a bitter argument followed. Mr. G's impotence was more severe from that time on. He recognized that these episodes caused him to lose self-confidence and he feared failure to perform sexually after this incident. Sometimes he drank intentionally to reduce his anxiety on an evening when sexual relations were anticipated, but the alcohol often seemed to limit his sexual capacity. They both recalled only three attempts at intercourse during the last 2 months; he avoided sex for fear of failure and she for fear of frustration.

This history is not uncommon in sexual impotence. A man with some historical evidence of sexual inhibitions and self-doubts becomes persistently impotent following a frank sexual failure, even though it occurred for more or less sufficient reasons (e.g., temporary impotence following excessive drinking). A vicious circle sets in after the episode. The fear of sexual failure inhibits sexual arousal and erection, confirming the man's fears and causing the problem to persist. The usual behavioral treatment consists of explaining this mechanism to the patient and his partner and assigning them to a program in which the pressure to perform up to some standard is minimized and the man gradually regains his self-confidence. The first few sexual occasions after treatment begins may consist simply of mutual nongenital fondling, some sessions of genital fondling may follow, and so on. The notion is that increasing sexual arousal in such nonthreatening preliminary encounters will inhibit anxiety responses and allow further arousal to occur. Coitus is not attempted until the man feels secure about maintaining an erection. This technique of in vivo desensitization has been described in detail by behavior therapists and sex therapists (6). Mr. and Mrs. G appeared to understand this procedure and were ready and willing to undertake it.

Because of an out-of-town commitment, I did not see the couple for two weeks, at which time they reported that the procedure had failed completely. They had delayed attempting the procedure for almost a week; then, contrary to my instructions, Mr. G reverted to drinking before the remedial session. Mrs. G—also in contradiction to instructions—did not stop at nongenital fondling but went on to very direct manipulation of her husband's penis and, despite a waning erection, urged him to attempt intercourse. Recriminations followed, and there was a repetition of this whole sequence several nights later. Failures of a particular technique in the course of behavioral therapy often provide essential additional data in the assessment of the clincial problem. With this couple, the failure suggested the need to obtain a wider range of clinical information, i.e., to learn more about the interpersonal context in which the sexual dysfunction was occurring. This required several more sessions of detailed history taking and, more important, direct observation of the couple interacting in my office. These latter sessions were tape-recorded with the couple's knowledge and then analyzed.

The analysis of the tapes revealed that Mrs. G was more directly assertive and active in the relationship—both in a positive, engaging way and in a negative way, making critical remarks and demands about the solution of problems and the differences between her and her husband. The negative aspect of this assertiveness predominated, as became particularly clear on examination of two sessions recorded in my office. She accounted for about 80% of the remarks the couple made, both positive and negative. During these two 45-minute sessions she interrupted her husband a total of 34 times and he interrupted her on 7 occasions. Another feature of their communication was easily quantified and revealing: the number of critical and pejorative remarks made by each compared with the number of positive or neutral comments. The ratio was about 5 to 1 for both Mr. and Mrs. G. When confronted with this preponderance of negative and critical remarks, documented by the tapes, both agreed after some discussion that approximately the same ratio had characterized their communications in other situations during the previous few months. The picture that emerged was that Mr. G's lack of self-confidence and assertiveness extended beyond the sexual situation to their relationship in general. He responded to their disagreements, sexual and otherwise, by being silent, emotionally aloof, and distant, especially when she nagged and criticized. She responded to these traits by being more critical of his aloofness and what she called "his sexual problem."

Another mechanism emerged that is not uncommon in problems of sexual inadequacy in marriage. There was a maladaptive behavioral chain in their interactions, i.e., a recurring sequence of responses to each

other, each response serving as a discriminative stimulus for the next response member and as a secondary reinforcer for the previous response member (7). In this chain, Mr. G would sense pressure from his wife to perform sexually later in the evening. He would prepare himself by drinking. Mrs. G would then call attention to his drinking, suggesting that he was not totally desirable in this state and implying that he might fail. He would then in fact fail to maintain an erection and she would indicate subtly that her prediction was fulfilled. When he failed sexually, he sometimes attempted to bring her to orgasm by manual stimulation of the clitoris. However, she often objected to this on the basis that it was "unnatural." The result was continued frustration for her, which further justified her being hurt and added to his feeling of being put down and inadequate. The following day he would be remorseful and placating, disagreeing little with her decisions and demands in other areas of their life. Thus, the pattern would be reinforced.

All elements of the chain would not occur on every occasion. For example, there were times when she would not capitalize on his remorseful attitude following a sexual failure but rather look to him to take a stronger, more "masculine" position. However, such a behavioral chain may be especially resistant to extinction if some of its members are reinforced intermittently.

This expanded analysis of the clinical problem indicated the need for some additional behavioral interventions. The first was assertive training, a common behavioral procedure in which the patient learns to be appropriately assertive through corrective instructions, role playing, behavioral rehearsal, and related techniques (8). As is often the case, Mr. G needed to be more assertive in the expression of appropriate anger as well as positive, emotional responses. He was encouraged, with Mrs. G's knowledge and, in time, help, to express more directly his anger at her frequent nagging, her tendency to be overly controlling, etc. It is the expression of anger rather than simply a verbal counterattack that is important, since the latter usually leads only to an escalation of hostilities. Thus, for example, if his wife would subtly allude to his sexual failures, Mr. G would respond with a statement such as, "You know that can only make me feel worse and aggravate the problem. Why don't you say and do something positive and supportive?" He was also deficient, however, in demonstrating positive verbal and nonverbal expressions of affection and interest, whereas she, despite her frequent nagging and critical remarks, did approach him warmly at other times. This assertive training extended over four sessions. The second procedure used was behavioral contracting (9), which is especially helpful with couples whose relationship is such that each attempts to satisfy his needs from the other by largely negative contingencies of reinforcement (e.g., nagging and social withdrawal). Clearly, this couple, despite their earlier very positive relationship, were now in this unproductive posture. In behavioral contracting, each person explicitly states what he wants from the other and then a more propitious exchange of positive reinforcements is arranged. In this case, Mr. G agreed not to drink when a sexual encounter was anticipated and to make a minimal number of positive verbal and nonverbal affectionate responses toward Mrs. G every day. As her part of the contract, she agreed not to express any negative expectations about his past, present, or future sexual performance and not to make unilateral decisions in everyday matters that were more important to him and are usually the prerogative of the husband in our culture. Finally, they both agreed that should he fail to maintain an erection they were to work together to bring her to orgasm by manual or other stimulation. In order to be maximally effective, such behavioral contracts must be literally written out and agreed to in the presence of the therapist, and the degree of compliance of each partner is reviewed and discussed at subsequent treatment sessions. In addition to the amelioration of specific conflicts, the process of negotiating compromises and of becoming better aware of the needs of the partner is of therapeutic value in itself.

The couple undertook these various procedures, and over a period of months the relationship in general improved. However, the impotence persisted, and anxiety was still attached to sexual performance. Hence, some 5 months after the initial assessment, the original treatment procedure, a program of graded stimulation, was begun again. In the new interpersonal context this treatment strategy was effective and the impotence improved greatly within a few weeks. I continued to see the couple at less frequent intervals over the next 6 months to monitor their use of these various behavioral procedures. Some minor relapses did occur but were easily remedied by reinstituting the behavioral procedures.

DISCUSSION

This case study is presented not to demonstrate the efficacy of behavior therapy—although a good clinical result was obtained—but rather to demonstrate the distinguishing features of a behavioral approach. One mechanism that contributed to the patient's impotence was that sexual cues (antecedent stimuli) were eliciting anxiety, which in turn inhibited sexual arousal. When an attempt to countercondition these anxiety responses by a course of in vivo desensitization failed, a wider range of environmental factors was considered and more clinical data were systematically collected. Additional variables, largely imbedded in the couple's relationship, that were operating to maintain the problem of inadequate sexual performance were identified. Some of these were antecedent events (discriminative stimuli) and other were consequences of specific behaviors (reinforcing stimuli). Additional behavioral procedures including assertive training and behavioral contracting were then employed.

One might ask whether a more extensive assessment of the presenting problem of impotence at the outset might have revealed the forces operating in the marital relationship that contributed to the maintenance of the problem. If this had been the case, the initial focus of treatment would have been the relationship. However, there are two reasons for beginning with the more sexually focused procedure. First, it is economical to try the least time-consuming strategy initially and to conduct a more extensive assessment and multifaceted treatment program only if the clinical problem is not quickly resolved. Second, the use of a highly focused behavioral procedure also provides a powerful diagnostic and motivational test. As in this case, it may quickly expose resistances to treatment so that other, related features of the total clinical problem can be identified, assessed, and appropriately treated.

One procedure used in this case—helping the patient to overcome anxiety-mediated sexual impotence by a step-wise program of increasing sexual activity—might have been used by a sex therapist of different orientation. However, the whole approach to this clinical problem was behavioral to the extent that the analysis was multivariate and empirical and treatment consisted of the systematic application of principles of learning to modify observable and quantifiable segments of behavior that have a functional relationship to the patient's sexual performance. Sex therapy is behavior therapy to the extent that it follows this paradigm, i.e., deals comprehensively with the environmental, interpersonal, and organismic factors maintaining the sexual problem. To the extent that sex therapy does not deal with all these factors, it is a limited approach to the treatment of sexual dysfunction.

The Effects of the Sealed Record in Adoption

BY ARTHUR D. SOROSKY, M.D., ANNETTE BARAN, M.S.W., AND REUBEN PANNOR, M.S.W.

The authors found that 40 of 50 adult adoptees who had reunions with their birth parents found the experience satisfying. Only 10% of the birth parents reacted adversely, although negative responses were somewhat more common among the adoptive parents. These findings confirm the authors' belief that adoption practices, which in all but 4 states include permanent sealing of birth records, should be changed to recognize the life-long nature of adoption. Their recommendations include opening the records for adult adoptees, creation of agencies to be available to provide assistance and counseling for all involved (adoptees, their adoptive parents, and birth parents), and consideration of new adoption methods that would not require biological parents to forever relinquish their child and all knowledge of him/her at adoption.

MENTAL HEALTH specialists and adoption agencies are becoming aware of an increasing number of adult adoptees who are expressing questions and concerns about their genealogical background. Some have successfully searched for and experienced reunions with birth relatives from whom they have been separated since infancy. In the past, adoptees tended to suppress such feelings because of reluctance to hurt their adoptive parents or to intrude upon the privacy of their birth parents. This tendency was reinforced by adoption agencies' emphasis on the finality of the adoption process and by psychotherapists who viewed such interests in birth parents as indicative of underlying neurotic conflicts. In recent years, however, adoptees have organized into activist groups that have established a forum for the discussion of such issues and the provision of mutual support for searching for and encountering birth parents (1, 2). These activist groups are also in the process of bringing civil rights cases into the courts to test the constitutional legality of keeping the adoptee's original birth certificate sealed for life.

The sealed record is symbolic of a whole body of secrecy that grew over a long period of time when there was little self-criticism or evaluation by professionals in the field. Beginning in the late 1940s, laws were passed in most of the states requiring that information identifying birth parents be kept confidential and made available to adult adoptees only through special court order. At the present time, only Alabama, Arizona, Connecticut, and Kansas do not have such laws. Policies are quite different in Scotland (3), Finland (4), and Israel (5), where the legally emancipated adult adoptee, on production of evidence about himself, may have access to his original birth certificate. Also, in England and Wales the Children Act of 1975 provides that people aged 18 years and older may have access to their birth certificates after a mandatory interview with an adoption counselor and that people adopted after November 1975 may have access to their records after they reach 18 years without seeing a counselor.

The controversy over the statutes related to sealed records has aroused considerable interest within the legal profession. Katz (6) emphasized that the decision to give up a child for adoption is irrevocable and that the adoptive parent-child relationship assumes all the characteristics of a natural parent-child relationship. He agrees with Goldstein and associates (7), who believe that every effort should be made to safeguard the developing child's continuity of relationships and environmental influences. Other writers have attempted to weigh the rights of the adoptees as provided by the equal protection clause of the Fourteenth Amendment against the birth parents' and adoptive parents' constitutional rights to personal privacy (8–11).

It became clear to us after consulting numerous adoption agencies and legal experts that there was a need for a study to clarify many of these controversial issues and provide guidelines for the establishment of future adoption policy, both at the agency and court levels. It was our impression that the agencies were totally unprepared for the effect that a constitutional decision in favor of adoptees' rights to their original birth certificates would have on their attitudes and practices. Our research investigation, a collaborative effort between a psychiatrist in private practice and two experienced adoption social workers, began in late 1972.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

METHOD

Our investigation was greatly facilitated by a number of articles in the lay press that brought the issue of sealed records to the attention of large populations and requested interested readers to write in with their personal experiences and reactions. We then mailed questionnaires regarding the sealed record to all those individuals who responded to these requests and provided forwarding addresses. We arranged to interview those adoptees and birth parents who had already experienced a reunion. Unfortunately, this type of research does not lend itself to a careful scientific design with adequate controls. Furthermore, the study is limited by its dependence on individuals who had enough concern and interest to volunteer for interrogation and investigation. However, we felt that these obstacles should not deter our efforts to clarify issues of great concern to millions of people.

Although our initial research design focused on the sealed record and its implications, it soon became apparent that there was a need to reevaluate the institution of adoption and all of the concepts that had governed professional practice for so long. The sealed record was only the tip of the iceberg. Underneath the tip were many serious issues affecting the welfare of all members of the adoption triangle—adoptees, birth parents, and adoptive parents.

In a previous publication (12) we discussed our impression that adopted persons are vulnerable to the development of identity conflicts in late adolescence and young adulthood as an outgrowth of any of the following developmental difficulties: 1) disturbances in early object relations, 2) complications in the resolution of oedipal conflict, 3) prolongation of the "family romance" fantasy, and 4) "genealogical bewilderment." Interviews with hundreds of birth parents indicated that most of them seemed to be functioning well within marriage and as parents, but harbored deep emotional feelings and sharp memories of bearing and relinquishing a child for adoption (13, 14). Our discussions with adoptive parents revealed that many fear that a liberalization of the adoption statutes would result in a loss of their adopted child to the birth parents, even though there is no evidence to support these feelings (15, 16). It would appear that this anxiety represents a resurgence of the preadoption childless feeling of emptiness and the sense of inadequacy associated with infertility (17).

RESULTS

We reported previously (18) on our initial 11 cases of reunited adult adoptees and their birth parents. We have now expanded our survey to 50 cases. Our sample consists of 41 female and 9 male adoptees ranging in age from 20 to 77 (median=40), all of whom were adopted early in life by nonrelatives. Thirty-three (66%) had reunions with their birth mothers, 15 (30%) with both birth parents, and the remaining 2 (4%) with their birth fathers. In 32 cases (64%) additional contact was made with other birth relatives including siblings, cousins, aunts, uncles and grandparents. The adoptees ranged in age at the time of the reunion from 18 to 50 (median=31).

The decision to search for birth parents seems to have been precipitated by such factors as marriage, pregnancy or the birth of a child, N=18 (36%), death of the adoptive parents, N=7 (14%), genealogical concerns, N=9 (18%), late revelation of adoption, N=4 (8%), attaining adult legal status, N=1 (2%), the search for love and acceptance, N=2 (4%), exposure to publicity about the adoptee activist groups, N=4 (8%), and coincidental happenings, N=5 (10%). The length of the search ranged from a few days to 29 years, with a median of 11 months.

Forty-five (90%) of the adoptees were satisfied with the outcome of the reunion. Most reported a sense of closure, resolution of genealogical concerns, and diminished identity conflicts. Forty-one (82%) of the encountered birth parents were positive and accepting and only 5 (10%) reacted adversely to the reunion with their relinquished child. In contrast, many of the adoptive parents had difficulty initially adjusting to the experience. Eighteen (36%) of the adoptive parents were cooperative and understanding, 10 (20%) were mildly upset, and 5 (10%) were quite hurt. In the other cases the adoptive parents had either died or were not told about the reunion in order to spare them from possible pain.

It is interesting that 29 people (58%) discovered striking personality similarities and common interests with their birth relatives. Twenty-five (50%) of the adoptees developed meaningful relationships with their birth parents; 16 (32%) were satisfied to have only periodic contact following the initial visit. In 4 situations (8%) there was a very strained relationship following the reunion and in 3 (6%) there were no further contacts. In the final 2 cases, it is too soon to determine the outcome.

The data do not indicate that a poor relationship with the adoptive parents was a primary reason for making contact with the birth parents. Twenty subjects (40%) reported a good relationship with both adoptive parents and 15 (30%) described a good relationship with at least one of their adoptive parents. There was, however, a trend toward a late, disruptive revelation of the adoption in this group. The median age at which the group learned about their adoptive status was 7 years, but 12 (24%) found out after they were 12 years old. Sixteen (32%) of the adoptees learned about the adoption from persons other than their parents and 22 (44%) described the revelation as a traumatic experience. It seemed to make little difference as to how the adoption was arranged—approximately half of the cases were associated with agencies and the other half with private sources. It may be significant that 30 (60%) of the adoptees were raised as only children in their adoptive homes.

DISCUSSION

The statistical data and case histories of the adoptees who have successfully searched for their birth parents are in accord with our impression that adoptees are more vulnerable than nonadoptees to the development of identity conflicts in late adolescence and young adulthood. Many of these adoptees seem preoccupied with existential concerns and have a feeling of isolation and alienation resulting from the break in the continuity of life through the generations that their adoption represents. For some, the existing block to the past may create a feeling that there is a block to the future as well. The adoptee's identity formation must be viewed within the context of the life cycle, in which birth and death are linked unconsciously. This is evident in the frequency with which marriage, the birth of a child, or the death of the adoptive parents triggers an even greater sense of interest in the birth parents.

It would appear that very few adoptees are provided with enough background information to incorporate into their developing ego and sense of identity. This is often the result of a reluctance on the part of the adoptive parents to impart known information, especially of a negative nature, that might hurt the child. The adoptees, in turn, are often reluctant to ask genealogical questions because they sense their parents' insecurities in this area. Information given to adoptive couples at the time of adoption is scanty and usually descriptive of an immature, confused adolescent unwed mother and father. Adoptive parents are not provided with follow-up information as to what kind of people the biological parents have become 18 or 20 years later.

The desire for genealogical background information is probably shared by all adoptees, but it can become a burning issue for some, simply because they have bright, curious minds and approach all of life's mysteries in an intelligent, inquisitive manner; their search may have nothing to do with the quality of the adoptive relationship. This is not to say, however, that there are no adoptees who have an obsessive need to search for their birth parents because of neurotic problems or an emotionally barren relationship with their adoptive parents. We have encountered many adoptees who are perpetual searchers, always stopping short of a reunion. The search itself (along with the associated fantasies) is the significant process serving to hold their personalities together. It would appear that these individuals would almost prefer to live with their fantasies, a prolongation of the classic family romance theme, than to face the reality of a possibly disillusioning reunion with the birth parent.

The preponderance of only children in the sample suggests that a sense of loneliness and isolation in childhood may be another contributing factor in some of the cases. The trauma resulting from an uncomfortable or delayed revelation of adoption is yet another reason for the development of deep identity conflicts. What stands out most when we review the data, however, are the positive benefits the majority of the adoptees gain from the successful search. Few regretted the experience, and many were enriched by a new meaningful relationship with their genealogical forebears. More significantly, most reported a deeper sense of love and appreciation for their adoptive parents, whom they viewed as their true "psychological parents." Although some of the adoptive parents were upset and hurt by the reunion, permanent damage to the adoptive family relationship resulted in only a few cases. For the majority of the birth parents, the experience provided an opportunity to resolve old guilt feelings and to erase years of questioning about the fate of their relinquished child.

We believe it is time to reevaluate our current adoption policies in light of our new knowledge and awareness in this area. The premise that has governed the philosophy and practice in the field of adoption has been that the relinquishment of a child by his/her birth parents permanently severs all ties between them. Although the present standards of anonymity were developed as a safeguard to all of the parties involved in adoption, they may, in fact, have been the cause of insoluble problems.

We need to recognize that birth parents, especially mothers, have probably not resolved their feelings about giving up for adoption a child they have been told they can never see again. We must also recognize that adoptees may feel a greater lack of biological connection and continuity than has been realized in the past. Furthermore, the aura of secrecy has probably been more of a burden than a protection to adoptive parents. Adoption agencies have insisted that adoptees be told early and clearly about their adoption, yet they have provided little help to adoptive parents in dealing with the complicated feelings arising out of their adopted child's dual identity and they have not educated parents to understand and accept as nonthreatening their child's concerns and curiosity about genealogy.

It is our conviction that adult adoptees should have access to their birth records, if they so desire, when they reach the age of 18. In Scotland, Finland, and Israel this option has not been widely exercized by adoptees, and most of those who did obtain their records have been satisfied with the additional information provided, without feeling a need to search further. For those adoptees who are determined to find their birth parents, the information available in the original birth records may not be sufficient. In order to avoid situations wherein adoptees spend agonizing years and large sums of money tracking down trivial clues, we would support the idea of regional reunion registries, where adoptees and birth parents could express their interest in a reunion with the other.

In order for the registry to be efficient, it should operate in conjunction with a professional mediating and counseling board composed of mental health specialists (psychiatrists, psychologists, and adoption social

workers) and representatives from each sector of the adoption triangle—adoptees, adoptive parents, and birth parents. The board would provide necessary assistance and counseling to all persons involved in or affected by an adoption reunion. Whenever a request was made by either an adult adoptee or a birth parent, attempts would be made to contact the person sought. The board could also serve an arbitration function when one party desires a reunion and the other is resistant.

The role of the birth parents after the culmination of the adoption proceedings must be reconsidered. Birth parents have always had a more direct involvement with adoptive parents in private adoptions than in agency-arranged adoptions. There are healthy aspects to this policy that should be studied more carefully by adoption agencies. Allowing the birth and adoptive parents to meet one another at the time of the adoption enables both to assume a better reality position and diminishes the chances that either will have to resort to denial or projection to deal with the proceedings. We also feel that adoptive parents should be provided with continuing reports of the birth parents' welfare by the original adoption agency. The adoptive parents can use the information to answer their children's inevitable questions and thus minimize the chances that the adoptee will resort to excessive fantasizing in an attempt to fill in identity lacunae. Information should also be made available to the birth parents about their child's progress and development.

There are fewer babies available for adoption today as a result of improved contraception, liberalized abortion laws, and an increasing tendency for unwed mothers to keep and raise their children. In a previous presentation we discussed the concept of "open adoption," defined as "an adoption in which the birth parent meets the adoptive parents, participates in the separation and placement process, relinquishes all legal, moral and nurturing rights to the child, but retains the right to continuing contact and knowledge of the child's whereabouts and welfare" (19). This special type of arrangement, which should not be confused with opening the sealed records, would make a number of children available for adoption in those cases where the birth parents are unwilling to cut all ties to the child. Such an arrangement could never be expected to replace the traditional adoption, but it is our impression on the basis of the few open adoptions we have studied that it deserves serious consideration.

CONCLUSIONS

Professionals in the mental health field need to realize that past adoption practices have led to numerous psychological problems for adoptees, birth parents, and adoptive parents. Future adoption practices should address the continuing needs of individuals placed for adoption in the past and of their birth parents and adoptive parents, as well as develop a creative and open approach to meet the challenges of the future.

We recommend that the following changes be considered:

1. Opening the original birth records to adult adoptees and providing background and identifying information when requested.
2. Establishing appropriate agencies that would be available to intercede on behalf of those adult adoptees or birth parents who wish to effect a reunion.
3. Continuing commitment by adoption agencies to all members of the adoption triangle for as long as necessary, including the provision of viable, current information to any of these parties. This involves reestablishment and continuation of contact by the agency with the adoptive family and the birth parents.
4. Counseling services which recognize that adoption is a life-long process.
5. Consideration of new adoption alternatives to provide stable homes and families for children who would not be relinquished otherwise.

Above all, it is essential for us to realize that openness and honesty must replace the secrecy and anonymity that have prevailed in adoption practices. We hope that the controversy over sealed records, which has brought these issues to the fore, will enable us to develop sounder practices to meet both past and future needs of millions of people whose lives are touched by adoption.

Prompt Publication Policy

The *Journal* would like to remind authors who are particularly interested in early publication (whether to establish priority of an idea, reveal innovative results of new research, or for other pressing reasons) of its prompt publication policy. Under this policy, short (maximum of six double-spaced pages) manuscripts will be considered for publication in the Brief Communications section of the first available issue. These manuscripts must still undergo expert scrutiny before being accepted, and two months must be allowed for the printing process. However, the time required for publication of these short articles can be lessened considerably.

Authors who would like to have their manuscripts considered under this policy should indicate this desire, as well as the reasons for it, when they submit their manuscripts.

The Course of Development of Mania in Patients with Recurrent Depression

BY DAVID L. DUNNER, M.D., JOSEPH L. FLEISS, PH.D., AND RONALD R. FIEVE, M.D.

The authors attempted to assess the extent to which bipolar patients are misdiagnosed as unipolar by evaluating the development of mania in patients who had recognized bipolar illness and by means of follow-up data on patients who had recurrent depressions. Mania occurred early in the course of bipolar illness: almost 80% of the bipolar patients were initially hospitalized for mania. Follow-up data and theoretically based calculations suggest that the chance of a patient with recurrent depressions becoming bipolar is about 5%. Based on these findings, the authors make suggestions for the classification of unipolar patients.

IT HAS BEEN SUGGESTED that patients with affective illness can be separated into at least two groups—bipolar (those patients with depression and mania) and unipolar (those patients with depression only). This classification system was initially proposed on clinical grounds and later supported with data from genetic, biological, and pharmacological studies of depression (1).

The criteria for bipolar affective illness can be generally agreed upon because mania is such a distinctive feature of the illness. However, there is less agreement among researchers as to which patients should be diagnosed as unipolar. For example, Perris (2) included in his studies only those patients who had had three episodes of depression, whereas Angst (3) and Winokur and associates (4) included as unipolar those patients who had had only one depressive episode. Furthermore, studies from the National Institute of Mental Health and the New York State Psychiatric Institute (5, 6) have supported the separation of patients with depression and hypomania but not mania (bipolar II) from both unipolar and other bipolar (bipolar I) patients.

Dr. Dunner is Research Psychiatrist and Dr. Fieve is Chief of Psychiatric Research, Lithium Clinic and Metabolic Research Unit, New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032. Dr. Fleiss is Associate Research Scientist, Biometrics Research Unit, New York State Department of Mental Hygiene, New York, N.Y. The authors are also with Columbia University College of Physicians and Surgeons, New York, N.Y., where Dr. Dunner is Assistant Professor of Clinical Psychiatry, Dr. Fleiss is Associate Professor of Biostatistics, and Dr. Fieve is Professor of Clinical Psychiatry.

This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grant MH-21586 from the National Institute of Mental Health.

The reason for the concern about diagnostic precision in the affective disorders is the need to define populations of greater homogeneity for clinical, genetic, and biological studies. Since some patients classified as unipolar or bipolar II may have a tendency to develop mania during the course of their illness (i.e., to become bipolar I), data regarding unipolar and bipolar II patients may not apply to truly homogeneous populations.

In this report we present data from our clinic regarding the development of mania in bipolar I patients whose initial affective episodes were depressions. The data are used to estimate the degree of heterogeneity in samples of patients with affective disorders.

METHOD

The research and clinical records of over 500 patients who had attended the lithium clinic at the New York State Psychiatric Institute as of January 1, 1974, were reviewed for diagnosis and clinical course. In order to be included in this study as bipolar I subjects, patients had to meet the criteria of Feighner and associates (7) for primary affective disorder and had to have been hospitalized at least once specifically for a manic episode. (We included in our bipolar I group patients Perris [2] classified as "unipolar manics.") In addition, the patients' records had to be sufficiently detailed to determine their age at first hospitalization and the dates and characteristics of subsequent affective episodes. The cohort thus included patients eventually diagnosed as bipolar I but who might have been diagnosed as unipolar or as bipolar II at the time of their initial hospitalization.

Our criteria for a diagnosis of bipolar II illness were 1) primary affective disorder according to the criteria of Feighner and associates (7); 2) hospitalization for depression; 3) periods of hypomania of longer than 2 days' duration, characterized by euphoria and two other symptoms (including hyperactivity, pressured speech, flight of ideas, grandiosity, decreased sleep, and distractibility); and 4) no hospitalizations for hypomania. Our criteria for a diagnosis of unipolar illness were 1) primary affective disorder, 2) at least one hospitalization for depression, and 3) failure to meet the criteria for hypomania described for bipolar II patients.

Data from the following two patient groups are presented: a retrospective study of 152 bipolar I patients

and a prospective study of 102 bipolar II and unipolar patients. The 152 bipolar I patients were obtained after excluding 21 other bipolar I patients whose records regarding initial hospitalization and subsequent course were not sufficiently clear for their inclusion in this study. Two of the 152 patients were diagnosed as bipolar II at the time of their initial attendance at our clinic and were hospitalized for mania during their clinic treatment. The remaining 150 patients were diagnosed as bipolar I at their initial clinic attendance on the basis of their histories. The 102 patients who were diagnosed as either recurrent unipolar depressives (N=31) or bipolar II (N=71) when first seen in the lithium clinic were treated in the clinic for varying periods of time (from 6 months to over 5 years).

Data were analyzed using the life table method, with follow-up beginning with the index hospitalization and continuing until the patient was hospitalized for mania. Bayes' theorem (8) was then applied to estimate the proportion of a sample of putative unipolar patients who were actually bipolar.

RESULTS

Retrospective Data

Table 1 presents some characteristics of the bipolar I patients. There was no significant male/female difference for the 152 bipolar I patients with respect to whether the first hospitalization was for a manic or depressive episode. The initial hospitalization represented the onset of affective disorder in about two-thirds of the cases. That is, about one-third of all patients reported treatment for or symptoms of hypomania or depression 6 months or more before their first hospitalization. An onset of mania versus depression did not differentiate patients as to whether the hospitalization represented their onset of illness or not. The mean age of onset (initial hospitalization) was about 30 years for both men and women and for those hospitalized first for mania and for depression.

The initial hospitalization for 107 patients was for treatment of a manic episode. An additional 13 patients were initially hospitalized for depression and became manic while hospitalized or were discharged and soon thereafter rehospitalized for mania. Thus 79% of the sample of patients who were eventually hospitalized for mania (bipolar I) could have been diagnosed as bipolar I at the time of the completion of the affective attack that led to their initial hospitalization.

The remaining 32 bipolar I patients were initially hospitalized for depression and may have had histories of intervening depressive episodes before being hospitalized for mania. Such patients would have been diagnosed as unipolar or bipolar II before their hospitalization for mania, at which time they would have been rediagnosed as bipolar I. The life table analysis (figure 1) shows that all of these patients had been hospitalized for mania within 28 years of their initial hospitalization for depression; their probability of being hospitalized for mania within 10 years of their initial hospitalization was 0.84.

TABLE 1
Characteristics of the Bipolar I Sample

Item	Number	Age		Age of Onset	
		Mean	SD	Mean	SD
Initial hospitalization for mania					
Men	70	41.8	13.1	30.5	11.6
Women	50	43.5	11.0	30.0	9.5
Later hospitalization for mania					
Men	13	45.8	14.7	34.8	13.5
Women	19	44.5	9.9	29.3	8.6

Cumulative data regarding intervening episodes of depression from the time of initial hospitalization for depression until the first hospitalization for mania are presented in figure 2. The probability that the next affective episode would be a manic attack leading to hospitalization was 0.44, and the probability of being hospitalized for mania before four intervening episodes of depression had occurred was 0.94.

The cumulative probabilities in figures 1 and 2 apply to the 21% of all bipolar I patients whose initial hospitalization was for depression only. The values must therefore be multiplied by 0.21 in order for them to apply to the bipolar I sample as a whole. Even then, the results are not in a form that is directly applicable to estimating the degrees of heterogeneity in variously defined samples of unipolar patients. What is needed is an estimate of the proportion of patients, out of all of those who will ultimately become bipolar I, who will first suffer a specified number of depressive episodes.

In appendix 1 some estimates are derived of the degree of heterogeneity in variously defined samples of unipolar patients. The degree of heterogeneity is 5% or lower whether we take either one or two as the minimum number of depressive episodes in defining unipolar illness.

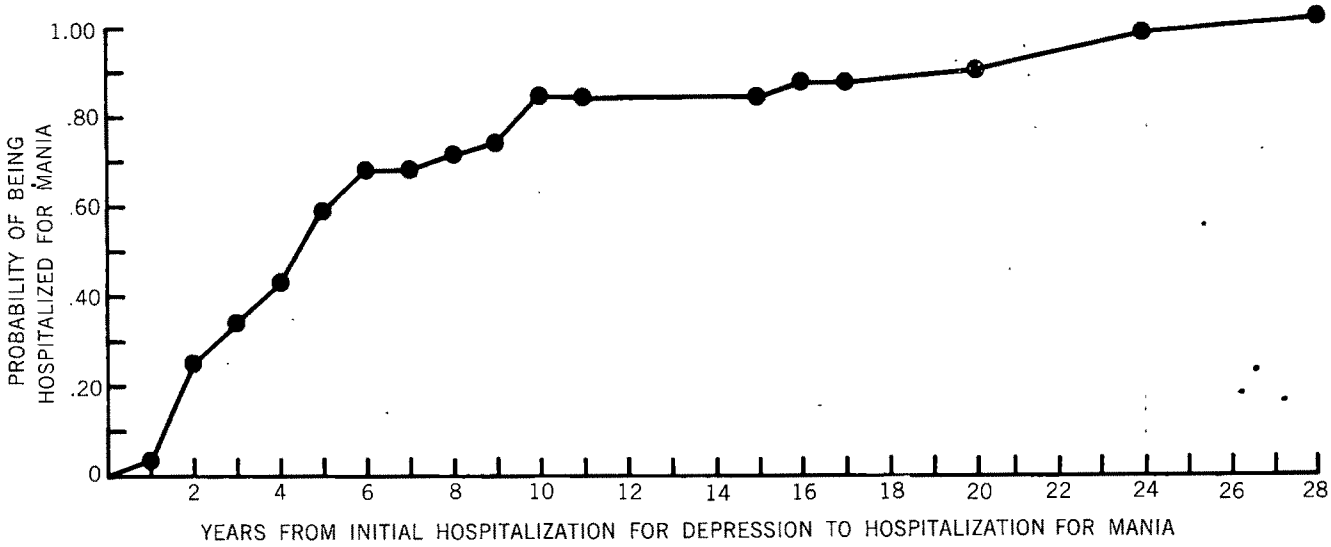
Prospective Data

During the period of direct follow-up of the 102 bipolar II and unipolar patients in our clinic, 2 of these patients, both bipolar II, were hospitalized for mania. One patient became bipolar I in the first year and the second patient in the second year of direct observation. The probability of converting to bipolar I, using the life table method, was 0.04 through the second year. Twenty-five of the original 102 patients were followed into the third year without developing a mania that required hospitalization.

DISCUSSION

The ideal determination of the development of mania in a depressive population would entail a prospective follow-up of a large number of patients who

FIGURE 1
Probability of Being Hospitalized for Mania for 32 Patients Who Were Initially Hospitalized for Depression and Followed Over Time



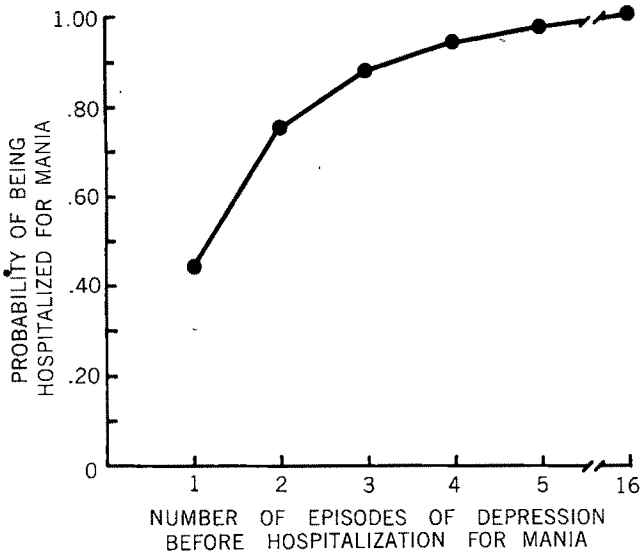


FIGURE 2
Probability of Being Hospitalized for Mania for 32 Patients Who Were Initially Hospitalized for Depression and Followed Through Other Depressive Episodes

entered the study at the time of their initial depressive episode. This cohort should be representative of the relative population frequencies of bipolar and unipolar disease, and the length of follow-up should be of sufficient duration that the vast majority of patients who will develop mania will have the opportunity to do so. Furthermore, the patients should not receive chronic medication, such as lithium carbonate or tricyclic antidepressants, which may alter the natural course of illness.

Given that this ideal study cannot be accomplished under present circumstances, one is left with a variety of retrospective designs to answer the question of how many depressive episodes should be required before reasonable certainty can be given to a diagnosis of unipolar illness. We have approached this problem by studying a large number of patients who were known to have bipolar illness (bipolar I). Seventy-nine percent of these patients were bipolar at the time of their initial hospitalized episode, which represented the onset of their illness in two-thirds of the cases. The remaining 32 patients were initially hospitalized for depression and later for mania. The probability of their being hospitalized for mania is a function of both time and the number of intervening episodes of depression. The data from these 32 patients suggest that the vast majority developed mania within 10 years of their initial hospitalization or before having experienced three subsequent episodes of depression. Thus severe mania tends to occur early in the course of bipolar illness.

The probabilities derived from the retrospective data for the bipolar I series correspond well to the prospective data for the bipolar II and unipolar series as well as to the data from the "Iowa 500" series (9). In our own prospective data, the probability of developing mania was 0.04 over a 2-year period for 102 patients who initially presented with recurrent unipolar or bipolar II illness. Furthermore, since the 2 patients who developed mania were bipolar II rather than unipolar, the exclusion of patients with histories of hypomania from samples of unipolar depressive patients would seem to produce greater homogeneity of the unipolar depressive population.

Winokur and Morrison (9) reported the results of a follow-up study of 225 depressive patients from the "Iowa 500" series. Nine of these patients showed signs of mania during the course of a follow-up of from 1 month to 20 years, and 8 of them had a manic episode within 3 years of their index admission. The authors

concluded that the chance of patients diagnosed as unipolar later becoming bipolar was less than 5%, a value we have confirmed.

Thus, based on the data from the course of development of severe mania in a bipolar population, we suggest that the probability of a unipolar depressive group being "contaminated" with patients who will later develop bipolar illness is small and can be further reduced by excluding those patients who have had hypomanic episodes. We also suggest that patients not be considered unipolar until they have been followed for about 6 months after their initial depressive hospitalization to ensure that this episode is not a pre-manic-depressive attack. Although we agree with Perris that patients with three depressive episodes are less likely to develop mania than patients who have had fewer attacks, the degree of homogeneity attained by employing this criterion seems to be outweighed by the loss of sample size necessary to achieve the criterion of three episodes.

APPENDIX 1
Method for Estimating the Degree of Heterogeneity in Samples of Unipolar Patients

The cumulative probabilities in figures 1 and 2 apply to the 21% of all bipolar I patients whose initial hospitalization was for depression only. The values must therefore be multiplied by 0.21 in order for them to apply to the bipolar I sample as a whole. Even then, the results are not in a form to be directly applicable to estimating the degrees of heterogeneity in variously defined samples of unipolar patients. What is desired is P (BPI/k): the proportion of patients, out of all of those who have suffered k or more consecutive depressive episodes with no intervening manic episodes, who will yet suffer a manic episode (i.e., become bipolar I). The data at hand provide the converse probability of P(k/BPI): the proportion of patients, out of all of those who will ultimately become bipolar I, who will first suffer k or more depressive episodes. P (k/BPI) is found by multiplying 0.21 by the complement of the probability in figure 2 corresponding to k-1.

Bayes' theorem provides a solution to the problem. Let P (k/Other) denote the proportion of patients, out of all of those who do not ultimately become bipolar I, i.e., remain unipolar or bipolar II, who will first suffer k or more depressive episodes, and let p denote the proportion of the present and ultimate bipolar I patients in the population of patients with primary affective illness. By Bayes' theorem,

$$P(BPI/k)=\frac{P(k/BPI)p}{P(k/BPI)p + P(k/Other)(1-p)}$$

Perris (2) found that about 20% of hospitalized affectively ill patients had bipolar illness (bipolar I illness according to our definition), so we can set $p=0.20$ and $1-p=0.80$. To our knowledge, good estimates are not available of P (k/Other) for values of $k>1$; for $k=1$, this probability is obviously 1.00.

We can make some estimates of the degree of contamination, i.e., P(BPI/k), in variously defined samples of unipolar patients for some reasonable values of P(k/Other), the proportion of nonbipolar I affectively ill patients who suffer k or more depressive episodes.

If $k\geq 1$, $P(k/Other)=1.00$ and $P(BPI/k)=0.050$.
If $k\geq 2$, $P(k/Other)=0.60$ and $P(BPI/k)=0.047$.

It is clear that the degree of contamination is low no matter what minimum number of depressive episodes we take in defining unipolar illness.

Linguistic Performance in Vulnerable and Autistic Children and Their Mothers

BY SHELDON M. FRANK, M.A., M.D., DORIS A. ALLEN, ED.D., LORRAYNE STEIN, AND BEVERLY MYERS

The authors studied the language patterns of schizophrenic mothers and their 4-year-old children, and compared them with the speech of normal mothers and children and normal mothers with autistic children. They found that children of schizophrenic mothers showed lags in language development and language distortions less severe than but in some ways similar to those seen in autistic children. Schizophrenic mothers were more likely to produce more deficient and/or distorted language in interactions with their children. Mothers of autistic children produced language that was equal to or above that of mothers of normal children on most parameters and adjusted their language to the chronological rather than the linguistic age of the child.

EVIDENCE OF LINGUISTIC aberration in schizophrenic patients has been compiled from the time of the earliest clinical literature on this disorder. Broadened and refined investigation of language in schizophrenia continues in the work of such psycholinguists as Chaika (1), who found that many schizophrenic patients fail to make specific semantic and syntactic distinctions.

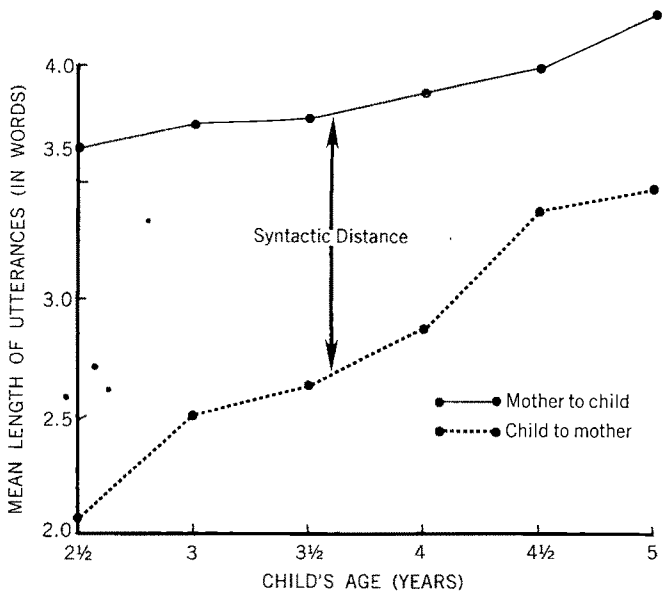
The increasing study in recent years of the role of the family in schizophrenia has included important findings on language and communication. Wynne (2) found high "communication deviance" scores in the fathers and mothers of adult schizophrenic and normal groups. These scores included variables pertaining to communicative intent, logic, semantics, and syntax.

Goldfarb (3) found that mothers of patients with childhood schizophrenia were poorer instruction-givers to their children than mothers of normal children; they were less responsive and provided sparser and more ambiguous information. His work has focused on childhood schizophrenia, which shows particularly strong and characteristic language deviations. This focus has been carried further by Shapiro (4), who found a predominance of echoing and of distorted, underdeveloped morphological and communicative parameters. The implications of Wynne and Goldfarb's work on the etiological nature of deviant parental communication in childhood schizophrenia are not supported by recent work by Howlin and associates (5, 6), whose preliminary findings showed that language of parents of autistic children is similar in communicative style to that of parents of nonpsychotic aphasic children.

Recent nonclinical psycholinguistic research has also focused on family communication while examining the normal process of language acquisition. In the late 1960s one of us (S.M.F.) collaborated with Alfred and Clara Baldwin and their associates on work in this area (7–9). We found that mothers adjust their language when speaking to their preschool child to a level much less complex than the one used in speaking with other adults but slightly more complex than the language level of the child. As measured both by MLU (mean length of utterance, in words) (10) and other linguistic parameters (11), the mother's complexity level rises with the rising level of the child from age 2½ to 5 years, remaining at what we have called a "syntactic distance," which diminishes slightly with the child's age.

This is shown in figure 1, which also illustrates how much a mother simplifies her speech when addressing her child instead of another adult; her MLU falls from 12.0 words to 3.7 words. Snow (12), Clarke-Stewart (13), and Nelson (14) have also found that mothers regularly modulate their language according to the child's level of language development.

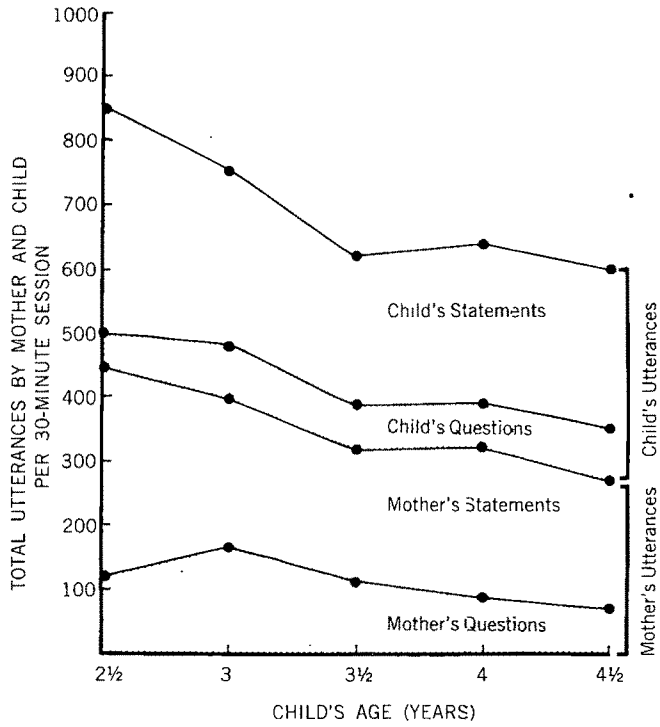
The data of Baldwin and Frank (7) and others (15–20) have led to a special focus on question-response behavior as an important aspect of normal mother-child



Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Frank is Assistant Professor, Department of Psychiatry, Millhauser Laboratories, HN 408, New York University Medical Center, 550 First Ave., New York, N.Y. 10016. Dr. Allen is Clinical Instructor in Psychiatry, Albert Einstein College of Medicine, Bronx, N.Y. When this paper was written, Ms. Stein and Ms. Myers were Research Assistants, Department of Psychiatry, New York University Medical Center; Ms. Stein is currently a student in the School of General Studies, Columbia Univ., New York, N.Y., and Ms. Myers is now a graduate student, Department of Linguistics, University of Michigan, Ann Arbor, Mich.

This work was supported by research grant U2366 from the Health Research Council of the City of New York and by the New York University Medical Center.



The authors would like to thank Carolyn Goodman, Ed.D., and her staff at the Bronx Psychiatric Center Parent and Child Education Program for referring subjects for this study.

interaction. In general, verbal interaction between mothers and their very young children (2 to 2½ years) consists of questioning, labeling, behavioral instructions, fantasy, and talk about the child's immediate desires.

As seen in figure 2, the mother dominates the interaction to the degree of contributing about 60% of the dialogue. By the time the child reaches its fourth year, the dialogue becomes more balanced, with the child contributing nearly 50%. More time is spent on communication of specific and general information and more on past and future as well as present circumstances. Fantasy diminishes as a focus. Questions are still an important means of interaction, but comprise only about one-fifth rather than one-third of the dialogue, and increasingly take on a more distanced and complex character.

When the child is 2½, most questions are of "Wh-type," comprised of "what," "who," "where," and similar questions. Within this Wh-type, the questions are predominantly ostensive, that is, they seek the label of a concrete object that is present. The interaction between a 4-year-old child and its mother contains a greater proportion of predicative questions. These deal with more complex issues such as manner, time, and cause (e.g., "how," "when," and "why") and are constructed in a more abstract manner, with the object not necessarily at hand.[1]

Our present work, a psychiatric-linguistic collaboration, attempts to study with linguistic sophistication families in which a parent is schizophrenic and a child is in the early stages of language development. We wanted to assess language development in a situation in which mother-child communication may be deviant and there is the possibility of prospective study of linguistic and psychological precursors of schizophrenia. We hypothesized that many vulnerable children would show quantitative and qualitative differences from the norm in language development and that related deviant qualities would be found in the parental language. Specifically, we predicted that vulnerable children would show lags in the development of syntax, questioning behavior, and responding behavior, and that their parents would fail to provide well-modulated norms in those aspects. We were also curious to see whether any deviant patterns would resemble those found in autistic children, the most linguistically deviant of "childhood schizophrenics."

We have concentrated on mothers who are schizophrenic simply because we were primarily referred subjects who were offspring of schizophrenic mothers, not fathers; certainly father-child communication deserves equally serious study.

METHOD

The data reported in this paper were collected as part of a longitudinal study of chronic schizophrenic

[1]These distinctions are more fully elaborated in reference (21), which discusses concepts proposed by Allen (20).

mothers and their preschool children. All of the mothers were outpatients living with and actively caring for their children. However, 7 of the 8 mothers studied had had inpatient care when their children were between 18 and 31 months of age, and all were being maintained on moderate doses of phenothiazine medication. All were native speakers of some dialect of American English and were of working class or welfare class status. Six of the 8 families had a father present in the home. The mean age of the children in this "vulnerable" group was 4 years.

A control group consisted of 8 normal mother-child pairs studied in an earlier collaboration (7, 8). This group was equivalent to the vulnerable group in socioeconomic class and age, and nearly identical in other characteristics.

A third group of 11 autistic children and their mothers was also studied. These families were of a slightly higher socioeconomic status but were otherwise comparable to the other groups. Diagnosis of autistic symptoms prior to age 2 was necessary for inclusion. The children were outpatients who could profit from a part-time therapeutic nursery and most had language abilities which placed them at the highly functioning end of the autistic spectrum.

All the mothers and their children were studied in a naturalistic playroom setting equipped with a standard set of toys including a doll house, books, puzzles, ring toss, and a toy telephone. The mothers were instructed to act with their children as they might at home. All 30-minute sessions were recorded on both audio and video tapes.

The tapes were transcribed to show all verbal interchanges between mothers and children as well as the nonlinguistic context in which each verbal exchange took place. In a preliminary analysis of the data, we looked at the following parameters for mothers and children in each of the three groups:

1. *Total number of utterances,* with proportion contributed by each member of the dyad.

2. *Mean length of utterance (MLU),* in number of words (10).

3. *Number of transformations.* (A measure of linguistic repertoire consisting of the number of different rules used in forming sentences more complex than a simple declarative statement—e.g., a question, a negation, a sentence with a conjunction [22].)

4. *Relationship of mother's to child's language:* a) "syntactic distance" (the difference between mother's and child's values in MLU's and number of transformation, and b) correlation coefficients between mother's and child's values on these parameters (ρ and Spearman rank order).

5. *Questioning behavior:* number and types of questions employed, and time orientation (now versus not now).

6. *Responding behavior:* proportion of "good responses" (appropriate to the nature of the question) and of nonresponses to the other's questions.

RESULTS

Linguistic Production in Vulnerable Children

The vulnerable children spoke less than did the normal group (see table 1). Although the percentage contributed by the child was not significantly lower, we observed a much wider range in this group, including 3 mother-child pairs who showed patterns of nearly total silence, overwhelming mother-dominated (76%) interaction, or overwhelming child-dominated (85%) interaction. (None of these patterns was seen in the normal group.) The trend in the remaining dyads was toward a stronger-than-normal mother dominance for this age. The vulnerable children's language had shorter MLUs and significantly fewer transformations than the normal children's. Moreover, language stages, calculated according to Brown (10), were one to three levels below normal in all but 1 child. These language levels, estimated to be about one year behind normal, may even be overestimated because of the children's tendency to overemploy a small number of transformational types.

Linguistic Production in Schizophrenic Mothers

Table 2 shows that these mothers spoke only slightly less frequently to their children than did the normal group, but that their structural level was significantly simpler. Thus it appears that they simplified their language when speaking to their developing (and language-deviant) children. However, a look at the values measuring syntactic distance shows that they may have exaggerated the optimal modulation and provided too little syntactic distance between themselves and their children. A clue that their children at this age may be especially sensitive to the language model provided appears in the right-hand portion of the table. Whereas in the vulnerable group there is a significant tendency for an individual child's complexity level to correlate directly with the mother's, this is not true for the normal group at this age.

Questioning Behavior of Vulnerable Pairs

As seen in tables 3 and 4, mothers in the vulnerable group tended to ask fewer questions per half hour than normal mothers, and their children asked about half as many as those in the normal group. Both mothers and children asked relatively few questions of the complex predicative form. The right-hand column combines mothers' and children's questions in considering their time character: more than 16 times as many of the normal group's questions involved past or future time. Moreover, only 1 of the vulnerable dyads engaged in fantasy interaction, and that mother-child pair did little else.

Responding Behavior of Vulnerable Pairs

As measured by our parameters of "good responses" and "nonresponses," there seemed to be no differences on means between mothers in the vulnerable and normal groups. There were trends toward

fewer good responses and more nonresponses in the vulnerable children.

Parameters in the Autistic Group

As we might expect, there was a significantly lower quantity and complexity of language production in the autistic children (see table 1). Their mothers, as shown in table 2, showed a trend toward an increased amount of verbal production. The mothers' complexity level looks lower than that of the normal group, but they provided a higher than normal amount of syntactic distance. That is, despite the low absolute level of complexity, their language is pitched at a relatively higher level in relation to their children's language. We found mothers' and children's language complexity to be highly correlated.

In their questioning (table 3), mothers of autistic children showed high values of total Wh questions but normal levels of Wh-predicative questions. Their children were below normal in both of these categories. The joint value for time character shows an overwhelming predominance of present time context. There is also equal to superior responding behavior by mothers of the autistic group, with many good responses and few nonresponses. Their children are dramatically deviant from normal levels on both measures, with directions reversed from those of their mothers—namely, few good responses and an extremely high level of nonresponses.

DISCUSSION

We have seen a lag in and distortion of language production in the group of 4-year-old children of schizophrenic mothers. Quantitatively, the abnormalities were always less than those seen in autistic children, but in the same direction from normal values. Qualitatively, none of the frequently seen autistic features (reversal of pronouns, lack of a vocative term for mother, echoes, abnormal prosody) was present, except in one child later diagnosed as schizophrenic. Neither were

there any of the gross abnormalities seen in adult schizophrenia, such as word salad, clang associations, or the poetic linguistic devices mentioned above. Despite the quite obvious qualitative differences between the language of the vulnerable and autistic children, both manifested such features as rigidity, perseveration, stereotypy, and restriction of repertoire and context. Examples of these traits were seen in one mother-child pair who exchanged a set of three or four questions and responses about the price of a toy ("How much?"; "Thirty-eight cents."; "Is that thirty-eight cents?") for a major portion of their 30-minute session.

A major feature of the vulnerable group was the presence of these abnormal qualities in the communicative language of the mothers as well as that of their children. Whereas a normal group mother might ask elaborate ostensive questions such as "Who is that little boy riding on the truck?" and rephrase the question if not answered, the schizophrenic mother would ask a simple "What's this?" and turn to a different object and question if not responded to. Furthermore, fully one-third of the times a schizophrenic mother asked a question she did not allow the child time to respond; she looked away, changed the subject, or asked further questions. The fact that our response categories in their present form do not yet measure this tendency, as well as a qualitatively different "feel" to responses in the vulnerable group, has led us (in other work in progress) to subdivide the global categories of good response and nonresponse into measures such as appropriateness, correctness, and no time given for response. We will test our hypothesis that vulnerable and normal groups are farther apart on some of these more specific parameters. Despite the limitations of the present global categories, however, some striking differences were seen.

Subsequent to this study, one child in the vulnerable group was independently diagnosed as schizophrenic. In retrospect, we found that her mother had had the highest percentage of nonresponses (49%), and had asked the highest percentage of Wh questions (61%);

however, she also asked the lowest percentage of Wh-predicative questions (19%)—i.e., more than four-fifths of her Wh questions were requests for a label. Her child's language level, typical for the vulnerable group, did not warrant this simplicity. In this case and others, we may add infantilization and lack of mother-child coordination to the abnormal psycholinguistic qualities seen in the vulnerable group. Our preliminary conclusion about this child and others of her group is that she is being given a deficient, distorted, and mismatched language model by the mother, which contributes to her own developing language deficiency.

The group of mothers of autistic children showed, by contrast, a normal to superior level in all parameters studied. Typical of these were good responses, in which 5 of 7 mothers scored over 70%, and syntactic distance, in which 9 of 11 pitched their language to a level one or two words higher than their children's level of language complexity. It is interesting that the 2 mothers who were outside this range—one lower, one higher—also had the fewest good responses. By comparison, 5 of 8 mothers in the vulnerable group had fewer than 44% good responses, and 6 of 8 had less than one-word syntactic distance. The only 2 mothers who made 100% good responses were both in the autistic group. Both a didactic aim and a pitch at the chronological—rather than the linguistic—age of the child can be concluded both from these results and from observer impressions of their interactions.

In our preliminary analysis of the autistic group, we see the high mother-child complexity correlation as comprised largely of the mother's "tuning-in" to her developing child, just as we feel that much of the high mother-child correlation in the vulnerable group was a result of the child's tuning-in to the mother. That the mothers in the autistic group did not pitch their language level quite as low in relation to their children's as normal group mothers is probably due to a "floor effect." That is, an adult cannot readily simplify her language below a certain natural lower limit if she is to say anything substantial. Therefore it would seem to be a combination of the adult's floor effect and the autistic child's extremely low MLU that accounts for the greater syntactic distance in the autistic group.

Among other possible sources of variance that need to be further explored are the following: 1) the heterogeneity of both abnormal groups, especially the autistic children, who have a verbal, questioning subgroup and a very silent subgroup; 2) the socioeconomic status of the autistic group, which is higher than that of the others; 3) the early mother-child separation due to mother's illness in the vulnerable group; 4) the influence of phenothiazine medication on communication; and 5) the effect of mental illness in general, rather than schizophrenia in particular, on family communication.

Longitudinal and statistical extension of our study should clarify and may modify our preliminary conclusions and their scope. Although the communication patterns in both experimental groups are at variance with those of the normal mothers and children, there are differences between the two disturbed populations as well as similarities. Mothers of autistic children function linguistically more like normal mothers than like schizophrenic mothers on most variables, in spite of the fact that their children are very deviant. That they adjust to their children's chronological rather than linguistic age has been noted. We cannot disprove that this is inappropriate rather than beneficially didactic, but it is striking that other studies, as well as these preliminary findings, indicate that mothers of autistic children are not schizophrenic in behavior or diagnosis, and, more important, that schizophrenic mothers do not appear to produce autistic children. This suggests the need for considerable reevaluation of the nature, etiology, and sequelae of communication disturbances in families in which one or more members is psychotic if our work is to have diagnostic and clinical relevance to psychiatry.

The Isaac Ray Award

The American Psychiatric Association invites nominations for the Isaac Ray Award for 1977. This award, in memory of Margaret Sutermeister, is presented to a person (psychiatrist, attorney, or someone from a discipline related to human behavior) who has made outstanding contributions to forensic psychiatry or to the psychiatric aspects of jurisprudence. The purpose of this award is to promote better understanding between the law and psychiatry. The award, which will be presented at the Convocation of Fellows at the Annual Meeting of the American Psychiatric Association in Toronto, Canada, in May of 1977, includes an honorarium of $2,000. The recipient agrees to present his or her work at an institution of higher learning (or other suitable location) and to present the manuscript for publication. The presentation will be located and timed to give maximum exposure to students and practitioners of law and medicine and to other professionals.

Nominations are requested by the deadline of October 1, 1976, from any interested professional, and may be submitted to: Naomi Goldstein, M.D., Chairperson, Isaac Ray Award Board, 15 West 81st St., New York, N.Y. 10024

A Symposium: Follow-Up Studies of Community Care

EDITED BY MILTON GREENBLATT, M.D., AND RICHARD D. BUDSON, M.D.

A session of the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975, was devoted to follow-up studies of community care. The participants were:

Paul R. Polak, M.D., Executive Director, Southwest Denver Community Mental Health Services, Inc., Denver, Colo., and Michael W. Kirby, Ph.D., Research Director, Polydrug Treatment Center, Denver General Hospital, Denver, Colo.

Leonard I. Stein, M.D., Director, Research Department, and Mary Ann Test, Ph.D., Associate Director of Research and Research Psychologist, Mendota Mental Health Institute, Madison, Wis.

Allan Beigel, M.D., Director, Southern Arizona Mental Health Center, and Associate Professor of Psychiatry, University of Arizona College of Medicine, Tucson, Ariz.; Steven Gurgevich, Ph.D., Director, Halfway House Demonstration Research Project, Southern Arizona Mental Health Center; Frank A. Petroni, Ph.D., Medical Sociologist, University of Arizona; and Alan I. Levenson, M.D., Professor and Head of the Department of Psychiatry, University of Arizona College of Medicine.

Richard D. Budson, M.D., Assistant Professor of Psychiatry, Harvard Medical School, Boston, Mass., and Associate Psychiatrist, McLean Hospital, Belmont, Mass.; Molly C. Grob, S.M., Director, Evaluative Service Unit, McLean Hospital, and Special Instructor in Social Work Research, Simmons College School of Social Work, Boston, Mass.; and Judith E. Singer, Ph.D., Codirector, Evaluative Service Unit, McLean Hospital, and Assistant Clinical Professor of Psychology, Department of Psychiatry, Harvard Medical School.

Loren R. Mosher, M.D., Chief, Center for Studies of Schizophrenia, National Institute of Mental Health, Rockville, Md., and Alma K. Menn, Soteria Project Director, Mental Research Institute, Palo Alto, Calif.

Milton Greenblatt, M.D., Professor of Psychiatry, University of California, Los Angeles, School of Medicine, Los Angeles, Calif., and Chief, Psychiatry Service, Veterans Administration Hospital, Sepulveda, Calif., was the discussant.

At the request of the Editor, Dr. Greenblatt and Dr. Budson, who was chairman and organizer of the session, have abstracted and commented on the papers presented at the session; the abstracts and comments appear below. Address reprint requests to Dr. Greenblatt at the Veterans Administration Hospital, Sepulveda, Calif. 91343.

IT IS A MATTER for celebration that after so many years of experimentation with community alternatives we finally have some valid attempts to assess specific models on a scientific basis. This collection of papers has great importance for all who are interested in finding better ways to treat patients than through hospitalization in remote institutions.

Follow-Up Evaluation of an Inpatient Alternative Program

BY PAUL R. POLAK, M.D., AND MICHAEL W. KIRBY, PH.D.

In this 18-month study, patients were randomly assigned to either home treatment (experimental group) or hospital treatment (control group). The same clinical team provided treatment to patients in both groups. No specific criteria were set for the exclusion of patients who were transient, psychotic, or had a history of previous psychiatric hospitalization.

In the inpatient alternative community home system, 6 families in southwest Denver each accepted up to 2 patients at a time for a base contract amount of $7.50 per patient per day for room, board, and care. Each family was assigned a clinical staff coordinator to assume responsibility for family supervision and support. The families also met regularly to learn from one another and from the staff. Instead of the 24-hour nursing rotation of a psychiatric hospital ward, psychiatric nurses provided 24-hour coverage to all of the homes. The nurses were backed up in turn by a psychiatrist on call.

Treatment in the community home alternative consisted mainly of crisis intervention, social system intervention, and tranquilization; treatment in the hospital consisted of the standard program provided at the Fort Logan Mental Health Center in Denver.

The effectiveness of therapeutic intervention was determined by a treatment effectiveness scale, a goal attainment scale, self-disclosure measures, and a community adjustment scale.

Ten of the 48 patients initially assigned to the experimental group were unable to be treated in the home because of severe clinical problems and were therefore eliminated from the home group. The final sample consisted of 38 home patients and 38 hospital patients.

At the 4-month follow-up the home group was rated

as distinctly superior to the hospital group on all measures, and the vast proportion of the home patients were pleased with the families with which they lived.

The data unequivocably favored intensive treatment in a private home rather than in a hospital. Treatment costs for the private home system were approximately two-thirds those of psychiatric hospitalization. Thus the findings favor community-based alternatives most impressively.

DRS. GREENBLATT AND BUDSON COMMENT

According to the authors the 10 patients who could not be treated in a private home did not affect their results significantly. The nature of the treatment in the hospital needs more explication if we are to evaluate results as a function of the intensity of personal assistance given patients. The fact that good results were achieved at a lower cost is certainly cause to rethink the use of hospitalization. The fact that the study attempted to treat all classes of patients with varying degrees of severity of illness in the community and was successful with the exception of a small group is very interesting. We await the longer follow-up promised by the authors.

Training in Community Living: One-Year Evaluation

BY LEONARD I. STEIN, M.D., AND MARY ANN TEST, PH.D.

"Training in Community Living" was a unique community treatment model in that hospitalization was virtually eliminated. The program accepted a random sample of adult patients presenting for admission to a public mental hospital regardless of their symptoms or social resources. Treatment took place totally in the community through actual staff contacts with patients, families, and community resources.

To implement the program, a staff of psychiatrists, psychologists, social workers, occupational therapists, nurses, and aides was retrained to work with patients, families, community agencies, and individuals to mobilize all possible support systems for the patients' benefit. The program was staffed from 7:00 a.m. to 11:00 p.m. 7 days a week. A member of the professional staff was on call at night to give 24-hour coverage as needed.

Every effort was made to avoid hospitalization except for patients who were suicidal or homicidal or who required such high doses of medication that a structured environment was necessary. However, if patients were hospitalized, this was included in the results. Thus no patients were excluded from the study on the basis of severity of symptoms.

The patients lived in independent settings scattered through the community. Treatment consisted of participation in a full schedule of daily activities; pharmacotherapy was used when appropriate. The therapeutic staff motivated and supported the patients by being present or available at all hours. Staff members were visitors in the patients' homes and neighborhoods. They taught patients daily living techniques, such as laundry upkeep, shopping, cooking, using restaurants, grooming, budgeting, and using transportation facilities. Patients were given intensive assistance in finding jobs or sheltered workshop placements, and the staff continued daily contact with the patients and their supervisors or employers to help with on-the-job problems. Leisure time was enhanced through the development of the patients' social skills; the staff arranged relevant community recreation and social activities. A "can-do" philosophy was transmitted from staff to patients, their assets were stressed, and their symptoms were played down. Daily contact of staff members with patients was emphasized initially and gradually diminished as patients progressed in the treatment program.

Work with families was directed primarily toward breaking pathological dependencies so that the "sick child" could become a responsible adult. With married patients', meetings were held with both patient and spouse. With unmarried patients, meetings were held with the family to describe and explain community programs, especially how the patients would be living without support from relatives. Parents and patients were given a great deal of help in order to maintain the separation; staff members were constantly available to families as well as patients. Conferences were held with every relevant community agency to promote behavior responsive to the patients' needs.

The study group consisted of all patients seeking admission to Mendota Mental Health Institute who lived in Dane County, Wis., who were between the ages of 18 and 62, and who did not have severe organic brain syndrome or primary alcoholism. These patients were randomly assigned to either the community treatment group or the control group. Control patients (N=65) were treated in the hospital for as long as deemed necessary and then referred to appropriate community agencies. The community treatment patients (N=65) received training in community living for 14 months. Assessments were carried out at the time of admission (baseline) and then every 4 months for 28 months in personal interviews by a research staff operating independently of the clinical teams.

Ratings included clinical measures of symptoms, community adjustment, self-esteem, amount of burden felt by family, and cost-benefit analysis of the two models.

Of the 65 patients in the experimental group, only 12 were hospitalized during the first year of the study, whereas 58 of the 65 patients in the control group were hospitalized. Twenty-one patients in the control group had more than one admission during the first year, compared with 3 patients in the experimental group.

Experimental patients spent very little time in psychiatric institutions in comparison with control patients, and they were not placed in penal institutions more often than the control patients. Experimental patients spent more time employed and more time in sheltered employment than did control patients. On global measures of satisfaction with life, the experimental patients seemed more satisfied than control patients at the 12-month follow-up. They also scored higher in self-esteem and manifested a more significant reduction in symptoms from baseline to 12 months than did control patients. The family burden measures showed a drop in the burden level for experimental patients but not for control patients. Detailed cost-benefit data are not yet fully analyzed; however, preliminary results indicate that the direct treatment costs for the average experimental patient were less than those for the average control patient.

DRS. GREENBLATT AND BUDSON COMMENT

The great values of this study lie in the uniqueness of the community program, in the long-term follow-up, and in the fact that community care patients were rated superior to control patients on all measures of adjustment. These results were achieved without shifting the burden of patient care to family or to penal system. Quality of life, level of adaptation, self-esteem, and personal satisfaction were all gratifyingly higher in the experimental group than in the control group. Such a resoundingly positive result gives pause for reconsideration of the value of conventional hospitalization. Intensive individual community support programs were not linked to any specific facility, which is what one normally visualizes when one speaks of community-based treatment. This is altogether an important and impressive piece of work.

Symptom Improvement Among Patients After Discharge

BY ALLAN BEIGEL, M.D., STEVEN GURGEVICH, PH.D., FRANK A. PETRONI, PH.D., AND ALAN I. LEVENSON, M.D.

This study describes symptom changes following discharge of 205 patients consecutively admitted to three different treatment units of the Southern Arizona Mental Health Center: 1) a halfway house program, 2) an outpatient clinic, and 3) a day program. Patients were between 18 and 50 years of age and expressed a desire to remain within the State of Arizona after discharge. There was no randomization of patients among the several threatment modalities because of a desire to study the delivery system as it actually was.

Symptom distress was measured by a checklist at admission, at discharge, at 2 months after discharge, and at 4 months after discharge. Scores on nine symptom dimensions were developed, plus two summary scores; i.e., a general symptom index and a positive symptom distress level.

The halfway house patients had symptom distress levels comparable to outpatients and day patients at admission. The predominant symptoms were depression, anxiety, and interpersonal sensitivity. Halfway house patients reported lower levels of somatic complaints at admission. At 4 months after discharge, the halfway house patients consistently showed the greatest reduction in symptom distress on all of the elements of the scale even though this improvement had not been noted at discharge. A lack of improvement during treatment was not necessarily a bad prognostic sign, and discharge decisions might have been governed by factors other than symptom improvement.

Patients in the halfway house reported higher levels of symptom distress on several dimensions during treatment compared with their baseline scores and compared with the symptom levels of outpatients and day patients during treatment.

The average elapsed time from admission to discharge of patients in the halfway house program was 25.5 weeks, compared with 13.6 weeks for patients in the day program and 4.9 weeks for patients in the outpatient program.

DRS. GREENBLATT AND BUDSON COMMENT

This study, unlike the two above, made no attempt at randomization. Selection factors resulting in referral to specific modalities were not made clear. The reasons for which therapists excluded patients from any particular modality of care were not spelled out. Another compounding factor in evaluating program effectiveness is the fact that length of stay within a given modality varied from 25.5 weeks to approximately 5 weeks. No cost figures were given.

A Follow-Up Study of Berkeley House, a Psychiatric Halfway House

BY RICHARD D. BUDSON, M.D., MOLLY C. GROB, S.M., AND JUDITH E. SINGER, PH.D.

This is a descriptive analysis of results of treatment of patients in a halfway house affiliated with a private teaching hospital (McLean Hospital, Belmont, Mass.). The halfway house, Berkeley House, situated in downtown Boston, had the capacity to shelter 23 residents and a married couple who managed the house. A warm family atmosphere plus an open system focused on integrating the house and its members with the community. Treatment consisted of weekly meetings of the residents, family-style dinners, and planned social ac-

tivities to support both residents and alumni. Residents were expected to be occupied productively during the day at work or school.

The subjects of the follow-up were 78 former residents, all but 1 of whom were white and most of whom were single, separated, or divorced and from the middle and upper socioeconomic classes. We were able to obtain data for 54 of the 78 former residents.

The follow-up was based on interviews of the 54 former residents by social work students under close supervision. The average time of follow-up was 15 months. The major problems noted by the patients when they were admitted to McLean Hospital included inability to function even minimally, interpersonal tensions, drug abuse, antisocial behavior, depression, and suicidal tendencies. The patients had been hospitalized an average of 12 months at McLean and 3 months elsewhere. During the McLean hospitalization there was a high concentration of psychotherapy and drug therapy. The average stay at Berkeley House was 7 months.

At the time of follow-up, 91% of the 54 former residents were living in the community and 9% were in the hospital. Most of the former residents in the community (N=49) were living independently, and 74% were either in school, employed, or functioning as homemakers at the time of follow-up. Eighty-seven percent of those working full-time (N=20) rated their work as good to excellent. Relationships with families were rated good by 60% of the former residents, and social adjustment was judged improved by 70%. The overall clinical status of 72% of the former residents was considered excellent, and only 1 patient had made a suicide attempt.

Seventy-eight percent of the former residents continued contact with Berkeley House after leaving, and many who left continued their contacts with other residents. In looking back on the Berkeley experience, 75% of 49 respondents said that Berkeley House helped them and 53% of 47 respondents said that it surely prevented their rehospitalization. They emphasized sharing, a sense of community, freedom, and the group gatherings.

DRS. GREENBLATT AND BUDSON COMMENT

The authors wisely considered the halfway house only one step in the total career of the patient. The community network that eventually took over also added greatly to the patients' rehabilitation.

In this study we note that 30% of the sample was lost, that there were no collateral appraisals from an independent team, and that the patients were mainly from the middle and upper classes. There was no attempt to relate this modality of treatment to other possible approaches to the same population. However, one of us gains the impression that real and important gains were made by those who were fortunate enough to receive treatment at Berkeley House.

Dinosaur or Astronaut? One-Year Follow-Up Data from the Soteria Project

BY LOREN R. MOSHER, M.D. AND ALMA K. MENN

This is a sophisticated study challenging three familiar hypotheses in the treatment of schizophrenic patients: 1) that short inpatient stays are good, 2) that antipsychotic drugs should be the mainstay of any treatment program, and 3) that treatment is best carried out in a medical context.

Thirty young schizophrenic patients aged 16–30, unmarried, separated, widowed, or divorced, and deemed in need of hospitalization (but with no more than one previous hospitalization lasting for 2 weeks or less) were assigned to Soteria House, and 27 similar patients from the same group were referred to an active inpatient treatment ward of a community mental health center. The assessment battery, which was extensive, was repeated at intervals up to 24 months after admission to the study. Community adjustment data from a variety of situations were reported. Self-report, family report, therapist report, and therapeutic process data were included.

Soteria was a 12-room house located on a busy street in a transitional neighborhood of a city in the San Francisco Bay area that was designated a poverty area. The house accommodated only 6 residents (patients) at a time. The staff included 6 nonprofessionals (2 were on duty at any one time), plus a project director and a one-fourth-time project psychiatrist. Admissions were at the rate of 1 or 2 residents a month. Staff and patients shared the responsibility for household maintenance, meal preparation, and cleanup. The project director acted as a friend, counselor, supervisor, and object of displaced angry feelings. The part-time project psychiatrist who supervised the staff was seen as a stable, reassuring person. Every effort was made by staff to treat the patient as a person capable of being understood and assisted in the integration of his psychosis into the continuity of his life.

Control patients were admitted to the community mental health center's inpatient service, which consisted of two locked wards of 30 beds each with an admission rate of about 250 patients a month and a staff: patient ratio of 1.5:1. All control patients received phenothiazines. They were assigned to psychotherapy, occupational therapy, crisis groups, couples groups, or survival groups as indicated. When discharged they could go to the regional centers nearest their homes for outpatient care, which included partial hospitalization, individual and family group therapies, and medication follow-up. An extensive board and care system, including halfway houses, was available.

Assessment of 32 pretreatment variables revealed only one significant difference between experimental and control patients. Soteria patients stayed significantly longer in their initial episode of care than control patients—167 days versus 21 days—and signifi-

cantly fewer Soteria patients received antipsychotic medication—17% versus 100%. Fewer experimental patients were readmitted during the first 6 months after their discharge.

At 1 year there was a trend favoring the experimental group in reduction of psychopathology, but both groups changed significantly in comparison with their pretreatment levels. Experimental patients were significantly healthier than control patients at discharge, but no difference between the groups was noted at 6 months after discharge. At 6 months after discharge more experimental patients were living alone or with peers—60% of 20 versus 4% of 24; this trend was maintained at 1 year but not at a statistical level of significance.

At 2 years after discharge the overall trends were not appreciably changed. There were no essential differences in psychopathology between the groups, but the psychosocial adjustment measures tended to favor the experimental group.

No harm was done by the relatively long period of residential treatment. Withholding drugs did no harm in terms of symptom level, symptom reduction over time, or level of community adjustment. The conscious attempt to minimize the disease with its attendant stigmatization was held at least partially responsible for the ability of experimental patients to leave their families of origin and to live independently.

DRS. GREENBLATT AND BUDSON COMMENT

The authors themselves raise questions about lack of randomization and small sample size—criticisms that will be met by a second study. To this may be added the notation that experimental patients stayed longer in Soteria than did control patients on hospital wards. Data published previously (1) indicated that the direct cost of the first 6 months in the treatment system was the same for both groups.

Discussion

BY MILTON GREENBLATT, M.D., AND
RICHARD D. BUDSON, M.D.

It is gratifying to note these several attempts to obtain conclusive evidence of the efficacy of transitional modalities of community care for seriously ill mental patients after many years of experience with community mental health programs. It is also gratifying that some of the major assumptions made by the planners of social and community treatment tend to be supported by these studies.

In general the papers suggest a wide spectrum of effective community care. Home care, family care, and halfway houses constitute some of the major modalities. Patients appear to have improved in self-esteem, in socialization, in ability to work, and in satisfaction with their lives; yet they were not necessarily more of a burden to their families. In addition, there is a lack of stigma and greater anonymity for patients treated in the community; some can be treated in the community at less cost than in hospitals. It would appear that the concept of treating patients in community facilities or in their homes early in their clinical course and without disrupting their ties to family, occupation, or community has been given positive support by these studies.

These welcome results have been shown to apply generally to relatively unselected or minimally selected mentally ill patients. That is to say, community alternatives can be applied to a wide range of clinical conditions, some of them very severe. Only a relatively few patients will have to be referred to sheltered, medically oriented environments. These few include patients with severe psychotic depression who are at risk of suicide, patients with brain damage, and patients who are dangerously aggressive toward themselves or others.

There is hope, too, that as we learn what is offered specifically in the way of therapy in a particular modality, individualized assignments to these modalities may be made and perhaps even better results achieved in the future.

All of the community treatment models need more study. In addition to the paper on Berkeley House abstracted here, one of us (R.D.B.) also recently reviewed 33 halfway houses established in Massachusetts (2). These houses were largely nonprofit, operated in affiliation with mental health agencies or associations, were located in urban settlements, and were usually established, it is good to note, without particular community harassment. One-fourth of the patients in these halfway houses came from the community and one-half from state hospitals. On discharge from the halfway houses 41% went to independent living, 26% to family homes, and only 17% back to state hospitals. Forty-nine percent were able to be in sheltered or competitive employment.

Rog and Raush (3) recently summarized 26 statistical reports on halfway houses, indicating that about 80% of the residents had been able to adjust to community living and that rehospitalization was lower after residence in a halfway house than might otherwise be expected.

This kind of evidence supports the necessity to include partial hospitalization community alternatives in future federal health care legislation. Inpatient psychiatric hospitalization should not be the only funded alternative domicile for people who must live outside their homes. The cost-effective data noted in some of the reports support the notion that this could be done economically.

It should be noted that these papers do not discuss a primary aspect of community psychiatry—the assumption of responsibility by a given clinical team for a de-

fined geographic area. Also to be encouraged are studies of risk groups, preventive intervention in risk groups, and total area planning for mental health based on sound epidemiological surveys. Development of appropriate new delivery approaches for these communities provides the great challenge for the future.

A final problem: once a demonstration of an effective modality has been made, how do we export it? For example, in the paper by Stein and Test an exciting difference was shown between experimental and control groups, but the method of treatment was based on community involvement of staff in a very intimate and supportive way. How can this be taught effectively to personnel in other locations? There tends to be a serious lag between new knowledge, however convincingly demonstrated, and the adoption of this knowledge. In this regard the work of Fairweather and associates (4) on the report of the community lodge idea to 255 mental hospitals is extraordinarily enlightening. They found that only a very small percentage of institutions they contacted adopted the lodge approach and that this often required their personal involvement in selling the idea. The Fairweather study is a real step forward in our understanding of the problem of export and adoption.

In regard to the studies abstracted here, one can only hope that our psychiatric colleagues will not only be enriched in their general knowledge of the potentialities of community psychiatry treatment but also take actual steps to try these experiments in their own locales. The trial of new approaches in several sites is sure to enrich and enlighten all of us as well as extend additional benefits to more and more patients.

A Five-Year Study of Brief Hospitalization

BY MARSHALL SWARTZBURG, M.D., AND ARTHUR SCHWARTZ, M.D.

The authors compare their experience with 4 years on a brief hospitalization unit based on crisis theory with a fifth year on the same unit based on a traditional psychiatric approach. In terms of demographic and diagnostic variables and rehospitalization rates, they found that the change in approach had no significant effect on the type of patient admitted or the treatment outcome. The fact that certain tasks necessary for rapid discharge were effectively performed accounted for the success of the unit.

THE GROWTH OF community mental health centers and the need to expand the delivery of care to an increasing number of patients have led to the development of a variety of clinical units that use the principles of crisis intervention. Originally postulated by Lindemann (1) and elaborated and popularized by Caplan (2), crisis intervention theory has been used as the guiding principle in a variety of clinical programs, such as emergency hotlines, emergency room care, and brief outpatient treatment. More specialized applications have included outpatient family crisis therapy (3, 4) and brief hospitalization units (5–7).

Although crisis intervention was geared initially to outpatient settings, it soon became obvious that seriously disturbed or suicidal patients often required hospitalization. Inpatient units structured to incorporate the principles of crisis intervention were therefore developed. At the same time that reports began to appear in the literature extolling the merits and successes of these brief treatment units (5, 6), the etiological significance in mental illness of life events upon which crisis theory is predicated came under increasing critical evaluation (8–11). There are few reports of the long-term performance of inpatient crisis intervention units and how they evolved as theory yielded to actual practice.

In this paper we will report on a five-year experience with one of the nation's pioneer brief treatment units (5). The successes and failures of this particular unit are used to derive implications for theory and practice.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

At the time this work was done, the authors were with the Department of Psychiatry, Yale University School of Medicine, New Haven, Conn. Dr. Swartzburg is now Associate Professor, Department of Psychiatry, the College of Medicine and Dentistry of New Jersey, Rutgers Medical School, Piscataway, N.J., and Dr. Schwartz is Associate Professor, Department of Psychiatry, Mount Sinai School of Medicine, the City University of New York, 5th Ave. and 100th St., New York, N.Y. 10029

THE SETTING

In 1967, a brief treatment inpatient unit called the Emergency Treatment Unit (ETU) was developed at the Connecticut Mental Health Center. The unit was designed to provide hospitalization for 3–5 days, followed by a 30-day outpatient follow-up by ward personnel. The duration of stay was deliberately limited to prevent regression and ensure the rapid return of patients to the community. The service was specifically organized to serve patients from lower socioeconomic classes who presented themselves at the emergency room of Yale-New Haven Hospital. The functioning of this unit during its early years has been previously reported; this unit was frequently visited by mental health professionals seeking to establish similar units in other institutions (5).

The ETU was housed on the first floor of the mental health center in an area opening directly onto the main lobby. The purpose of this design was to allow patients to mix with whoever chanced to be sitting in the lobby and thus to "diminish the tendency to perceive oneself as a mental patient in need of confinement" (5). There was a high staff to patient ratio, and the staff was highly trained and committed to the principles of crisis intervention.

The unit used a team approach that blurred traditional disciplinary roles. Therapy focused on the immediate precipitating issue. There was a bias toward admitting patients who presented with an acute and definable crisis. Personnel benefited from a feeling of high morale that ordinarily marks the start of new and innovative programs.

After four years of continual operation, a reorganization of the mental health center dramatically changed the unit. The unit was moved onto a traditional inpatient psychiatric ward with doors that could be and, in fact, were often locked. The setting was on the fourth floor, far removed from the lobby.

A new staff was assembled consisting primarily of nursing personnel from the traditional inpatient unit. The staff was unschooled in crisis intervention principles, mistrustful of the concept, and resentful of the change that had taken place on their service. In addition, the unit was denied its prior role in selecting

those patients deemed suitable for crisis intervention, and patients referred for hospitalization, regardless of their particular psychopathology or long-term prognosis, were admitted to the unit on a space-available basis. To meet the resultant increased demand for service, the number of beds available was approximately doubled, with a consequent reduction in the staff to patient ratio.

It now became possible to study whether the special characteristics that had been previously built into the unit based on crisis theory were, indeed, essential for the carrying out of an acute intervention program based on less than one week of hospitalization.

RESULTS

During the five-year period, 1,890 patients were admitted. Doubling the unit's bed capacity resulted in a yearly census of 480 as compared with a previous average yearly census of approximately 350—an increase of 37%.

The demographic characteristics of the patients treated remained constant throughout the five-year study period, despite the change in screening procedures and the increased number of beds. Of the patients admitted, 80% were white, 68% were female, and 60% were under 30 years of age.

Although data with respect to social class, determined according to Hollingshead's two-factor index (12), were not available for two of the four years prior to the change, the social class of the patients did not vary during the other three years. There is every reason to believe that social class remained constant throughout the five-year period; 75% of the patients came from classes IV or V.

A diagnostic breakdown of the patients revealed that approximatley 35% were psychotic—the vast majority (30%) carrying a diagnosis of schizophrenia and the rest (5%) with a diagnosis of affective disorder. Of the nonpsychotic patients (65%), 25% were diagnosed as having neurotic depression, 9% as having character disorders, 8% as having borderline states, 8% as having adjustment reactions, 3% as having other neuroses, and 4% as having organic brain syndrome. Alcoholism or drug dependence was the primary diagnosis for 6% of the patients, although these agents were abused by many of the other patients. There was no significant difference with respect to diagnosis before or after the change that took place in the unit.

Rehospitalization refers to the hospitalization of those patients who could not be discharged from the unit and were transferred to longer-term facilities or were rehospitalized at any facility during the 30-day outpatient follow-up period. During the four-year period preceding the change, 15% of the patients required transfer to another hospital and an additional 5% were rehospitalized during the 30-day follow-up, for a total rehospitalization rate of 20%. Following the change, 22% of the patients required transfer and 3% were rehospitalized during their follow-up, for a total of 25%. There is no significant difference between these figures.

The data reveal that the only significant demographic variable with respect to rehospitalization was sex—males had a significantly higher rehospitalization rate than females throughout the five-year period (32% versus 18%, $p<.001$, chi square, Yates' correction applied). Marital status, age, and race did not affect the rehospitalization rate.

The rehospitalization rate was approximately 40% for patients with schizophrenia and major affective disorders, and 32% of the alcoholic patients were rehospitalized. Patients diagnosed as having borderline states or character disorders had a rehospitalization rate of 20%. The rehospitalization rate for patients in all other diagnostic categories was 10% or less.

Although no data were available for the first four years reviewed, analysis of data from the last year revealed social class differences with respect to rehospitalization for patients with a nonpsychotic diagnosis. Twenty-five percent of the patients in classes I, II, and III were referred for further hospitalization, whereas only 10% of the patients in classes IV and V were so referred ($p<.02$, chi square, Yates' correction applied). There was no difference in this regard for patients who were psychotic.

DISCUSSION

Five years of experience with almost 2,000 patients demonstrate that brief hospitalizations can be of great value. Indeed, between 75% and 80% of all patients hospitalized on the ETU were successfully discharged. Although such findings appear to confirm the clinical applicability of crisis theory, careful assessment of the ETU raises questions as to which aspects of crisis theory were important with respect to the unit's functioning.

Crisis theory postulates that rapid and appropriate interventions in a time of a hazardous life situation can prevent the development of maladaptive coping mechanisms that may lead to regression into illness. By preventing the effects of adaptational failure and the resulting disability, crisis intervention is supposed to avoid the need for more extensive treatment at a later time. In addition, proponents of crisis theory postulate that resolution of the crisis can promote psychological growth and healthier adaptive patterns in the future.

Critics of crisis theory have pointed out that the theory implies that crises may be conceptualized and dealt with independent of the particular psychological or characterological traits of the individuals concerned (8). For this reason they question the relevance of the crisis theory approach to the real life situations confronting psychiatrists in emergency clinical settings. Defenders of crisis theory note that the theory assumes an external hazard and a "susceptible" individual interacting to produce a crisis. Since concepts

such as hazards and susceptibilities cannot be strictly defined, the meaning and applicability of crisis can be understood differently in different or even the same clinical settings. It is therefore important to identify those specific factors which resulted in the success of the ETU.

Although the theoretical set of the ward leadership changed from a broad adherence to crisis theory to a more traditional psychiatric outlook, the clinical focus was defined by the time limit placed on hospitalization. The clinical task was to treat those psychopathological and/or social factors which necessitated hospitalization. The abandonment of a ward setting specifically designed for crisis intervention and the screening procedures designed to select patients appropriate for crisis intervention had no significant effect on the type of patient admitted or the treatment outcome.

Consistently 40% of all schizophrenics who were admitted required rehospitalization—the crucial factor was severity of symptoms. Acute florid episodes invariably required further hospitalization. Our clinical observations agree with the reported findings that emotionally overactive, very suspicious, and severely disorganized patients require longer hospitalization than crisis units provide; similar results were found with those patients with affective psychoses. The clinical syndrome and its response to pharmacotherapy determined the outcome. This was true even when certain precipitating situations that may have played a role in the onset of the episode were easily resolved.

Schizophrenic patients whose adjustment outside the hospital was disrupted by life stresses or medication problems often presented with mild depressions, marital conflicts, symptoms of anxiety, and mild cognitive dysfunction. Reinstituting a proper medication regimen was often sufficient to abort the episode and allow discharge. Our clinical observations are also in agreement with those of Beck and Worthen (9), who found that schizophrenics admitted to a short-term inpatient service were less likely than other patients to have had a clear-cut precipitant or crisis that could account for their decompensations. These patients appear to get into difficulty with even the ordinary vicissitudes of life.

As might be expected, among the almost 50% of our patients with diagnoses of neurotic depression, borderline personality, and other character disorders, suicidal ideation or suicide attempts most commonly precipitated admission. Almost all of these individuals, including the neurotic depressives, had long histories of maladjustment to life stresses. Over 90% were recommended for further treatment after their 30-day follow-up.

The concept that a successful resolution of a crisis can foster psychological growth did not seem to apply to the majority of individuals with pervasively disruptive life-styles. However, crisis intervention theory provided the initial rationale for the development of the unit and was of heuristic value throughout the unit's history. The success of the unit can best be accounted for by the fact that certain tasks necessary for rapid discharge were effectively performed. These included critical clinical judgments about who could and could not be discharged and who represented lethal threats to themselves and others and a broad knowledge of referral and resource sources for patients within the community. The finding that significantly more patients in the upper three social classes who were not psychotic were referred for further hospitalization than patients of lower social class implies that when funds were available, dispositional choices approached a preconceived clinical ideal. Since the severity of the illness was the overriding factor in determining final outcome for psychotic patients, we found no difference in rate of rehospitalization with respect to social class.

Brief hospitalization units are best designed as component parts of a total care-giving system in which rehospitalization is seen not as a failure but rather one of many possible dispositions to be chosen in the best interest of the patient. In fact, in a system of mental health care that is becoming more varied and complex, rapidly matching a clinical situation with disposition and working to help the patient and his family accept that disposition are probably the basic reasons for the success of brief treatment units.

Lithium Prophylaxis of Depression in Bipolar I, Bipolar II, and Unipolar Patients

BY RONALD R. FIEVE, M.D., TURKAN KUMBARACI, PH.D., AND DAVID L. DUNNER, M.D.

The authors investigated lithium prophylaxis of depression in bipolar I (N=35), bipolar II (N=18), and unipolar I (N=28) outpatients. Depression indices included frequency of depressive episodes, three measures of severity, dropouts due to depression, and time in study. There were significantly fewer episodes and dropouts due to depression in the lithium-treated than in the placebo-treated bipolar I patients. Lithium was superior to placebo on all indices in the bipolar II group (although the sample size did not permit statistical analysis) and on 3 indices in the unipolar group. The authors believe that lithium prophylaxis of depression has been demonstrated in these three subtypes but note the need for further research, particularly in the use of tricyclic antidepressants.

THE EFFECTIVENESS of lithium therapy in acute mania is well established (1–6). Although several centers have reported positive results from the use of lithium to treat acute bipolar depression, this finding needs further confirmation, particularly in comparison to the use of tricyclic antidepressants (4, 7, 8). Lithium's therapeutic efficacy in unipolar depression remains virtually untested. The prophylactic effects of lithium carbonate in bipolar I manic and bipolar II hypomanic phases are also well documented (9–16). However, lithium prophylaxis of the depressed phases of bipolar I, bipolar II, and unipolar illness has not been sufficiently investigated in previous studies (17). This paper, which is based on data collected in outpatient studies conducted over a 4-year period, represents an attempt to fill this gap in our knowledge of lithium prophylaxis of depression in affective illness.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are with the New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032, where Dr. Fieve is Chief of Psychiatric Research, Lithium Clinic and Metabolic Research Unit, Dr. Kumbaraci is Biostatistician, and Dr. Dunner is Research Psychiatrist. Dr. Fieve is also Professor of Clinical Psychiatry, Columbia University College of Physicians and Surgeons, New York, N.Y., where Dr. Dunner is Assistant Professor of Clinical Psychiatry.

This work was supported by the New York State Department of Mental Hygiene, by Alcohol, Drug Abuse, and Mental Health Administration grant MH-21836 from the National Institute of Mental Health, and by the Millhauser Gift for Depression and Manic Depression.

METHOD

All patients were diagnosed independently by two psychiatrists and met the criteria of Feighner and associates (18) for primary affective disorder. Voluntary informed consent was obtained for all research procedures.

We define our patients as follows: bipolar I patients have been hospitalized for mania and have had mild to severe depressions; bipolar II patients have been hospitalized for depression and have a history of hypomania not requiring hospitalization; and unipolar recurrent depressive patients have had at least 1 depressive episode requiring hospitalization and have no history of mania or hypomania (17). Patients in all 3 subtypes have normal functioning between attacks.

Details of the methodology for our double-blind placebo studies of lithium have been reported elsewhere (12, 13, 16, 17). In general, patients were randomly assigned to the placebo or lithium group. The two groups received identical white capsules containing either lithium or placebo, depending on the patient's randomized assignment. At the time of admission to the study, all patients were symptom-free and were not being treated with antidepressants or tranquilizing medication.[1] The treating psychiatrist, nurses, and patients were unaware of the specific drug assignments. Throughout the trial, serum lithium levels were monitored every 4 weeks and the psychiatrists (who were given fictitious levels for the placebo patients) regulated dosages to maintain a level of 0.7–1.3 mEq/liter.

Each patient visited the clinic every 4 weeks and was interviewed by a psychiatric nursing team. Patients were rated for mania and depression on a modified Hamilton Rating Scale (19) and for depression on a 3-point global scale. When a patient was judged to be ill by the rating team, an additional assessment was made by the treating psychiatrist. If the psychiatrist prescribed additional medication, the patient was recorded as having had an affective episode. Antidepres-

[1]Fewer than one-third of the bipolar I and bipolar II patients had been previously treated with either lithium or imipramine.

sants or, if the episode was manic, antipsychotic drugs were prescribed. During this period, the experimental medication was continued, and every effort was made to keep the patient in the research protocol. The intent was to treat the episode as vigorously as possible with the best available standard medications while continuing administration of the appropriate experimental medication (lithium or placebo). When the episode ended, the additional medication was withdrawn and the patient continued to receive only the experimental medication.

Subjects

Bipolar I patients. Thirty-five patients were available for the 4-year analysis of lithium prophylaxis in bipolar I depression. This is the sample we described previously (12, 13) in 2½-year reports (October 1969 to February 1972), with the exclusion of 17 patients who were either bipolar II or rapid cyclers. In the lithium group, there were 11 men and 6 women (mean ages=53.1 and 44.3 years, respectively). The placebo group consisted of 8 men and 10 women (mean ages=39.6 and 46.5 years, respectively).

All patients were followed until March 1974. The cut-off point for inclusion in the randomized sample was November 1971 for 34 of the 35 bipolar I patients; 1 patient was added to the sample in March 1972. All bipolar I patients had a history of at least 2 episodes of affective disorder of at least 2 weeks duration and of sufficient severity to impair usual functioning in the 2 years prior to their entrance into the study. This report thus assesses lithium prophylaxis for periods of up to 4 years and 5 months.

Bipolar II patients. The sample of bipolar II patients consisted of 18 individuals. In the lithium group there were 2 men and 5 women (mean ages=58 and 50.2 years, respectively). The placebo group consisted of 5 men and 6 women (mean ages=55.2 and 49.2 years, respectively.) The criterion for inclusion was a history of at least 2 affective episodes in the 2 years prior to the study. Data from October 1969 to March 1974 were analyzed, and the cut-off point for entry into this study was November 1971. There were 2 rapid cyclers who remained in both the lithium and placebo groups; data for these patients were analyzed for all indices except duration and frequency of attacks.

Unipolar recurrent depressive patients. Twenty-eight patients with unipolar recurrent depression were studied. The criterion for inclusion was a history of at least 2 depressive episodes in the 5-year period before randomization (17). Data from December 1969 to March 1974 have been analyzed. The lithium group consisted of 1 man and 13 women (mean ages=60.0 and 43.3 years, respectively). In the placebo group, there were 2 men and 12 women (mean ages=64.5 and 54.4 years, respectively.)

Multiple Indices for Evaluation of Prophylaxis

The four following indices were used to evaluate depression prophylaxis:

1. Mean number of months in study.
2. Frequency of depressive episodes—the mean number of attacks per patient year was determined using the statistic described by Deming (20).
3. Severity of depression—determined by 1) depression ratings on a 3-point global rating scale (1.0=normothymia, 2.0=mild depression, and 3.0=severe depression) scored by nursing teams blind to the randomization code, 2) number of patients hospitalized, and 3) duration of depression, with the endpoint being return to normal mood and withdrawal of supplemental medication or time of dropout, if the latter occurred.
4. Number of dropouts due to depression.

RESULTS

Bipolar I Patients

Data on bipolar I patients are presented in table 1. Lithium-treated patients remained in the study longer than placebo-treated patients, primarily because placebo-treated patients dropped out due to mania. Several indices, including episodes per patient year and dropouts due to depression, demonstrated depression prophylaxis in the lithium group. The average duration of depressive episodes was 58 days for lithium patients and 48 days for placebo patients. This difference is not statistically significant. However, these results may reflect a methodological problem, since more placebo

* By Deming's statistic.

patients than lithium patients dropped out of the study. Therefore, data on duration of depressive episodes are less complete for the placebo patients.

Bipolar II Patients

As table 2 indicates, lithium prophylaxis was less clearly demonstrated for bipolar II patients than bipolar I patients on several indices. The data do favor lithium over placebo in terms of the length of time patients remained in the study. There were almost 50% fewer episodes of depression in the lithium group than the placebo group, although the number of patients in the lithium group is too small to appropriately apply Deming's statistic. Similarly, although the average duration of depressive episodes was 57 days for lithium patients versus 194 days for placebo patients, the sample size is too small to permit tests of statistical significance.

Four patients in the lithium group had episodes of depression and 1 patient dropped out of the clinic because of depression. In contrast, 7 patients in the placebo group had episodes of depression, and all 7 of the placebo dropouts were due to depression. The difference between numbers of dropouts due to depression in the lithium and placebo groups is statistically significant, indicating lithium prophylaxis of episodes of depression severe enough to cause patients to quit the research protocol.

Unipolar Recurrent Depressive Patients

Table 3 presents data on patients with unipolar recurrent depression. Lithium-treated patients stayed in the study longer and had fewer depressive attacks than placebo-treated patients. The mean depression rating also showed that lithium lessened the severity of depressive episodes.

DISCUSSION

Our findings of fewer depressive episodes and fewer dropouts due to depressive episodes in the lithium group indicate that lithium is highly effective in prophylaxis of the depressive phase for bipolar I patients. Similar findings based on single indices of depression (e.g., improvement versus no improvement and hospitalization versus no hospitalization) have been reported in a single-blind study from our group (21) and in other double-blind studies (9, 15). In our study, a large proportion of placebo-treated bipolar I patients experienced acute manic episodes and dropped out before experiencing any depressive episodes. This confounds the evaluation of lithium's action on the depressive phase of the illness.

The high percentage of dropouts due to mania is a potential bias in comparisons of duration and severity of depression in the lithium and placebo groups. Since information on severity and duration is less complete for placebo patients than lithium patients, any bias in results should tend to favor placebo. However, there are no significant differences between placebo and lithium on these measures in the bipolar I group. We suggest that under ideal conditions (no dropouts) there might be demonstrable differences in duration and severity of depression favoring lithium.

Data on the bipolar II patients also suggest lithium prophylaxis of the depressed phase on several indices. The frequency of depressive episodes in the lithium group was approximately half that of the placebo group, although there were too few patients to permit application of Deming's statistic. As with the bipolar I group, there was evidence that lithium attenuates the severity of depressions in that fewer lithium patients

than placebo patients dropped out due to depressive illness. Findings of fewer dropouts are consistently associated with lithium efficacy, and in the present study 57% of the lithium patients versus 18% of the placebo group remained in the research protocol until the end of the 4-year trial. Furthermore, the duration of depressions was considerably shorter in the lithium group than in the placebo group (57 days versus 194 days), although there were too few cases for statistical analysis. All of these indices indicate that lithium acts prophylactically on bipolar II depression and is superior to placebo.

It is of interest that the addition of data from 20 more bipolar II patients, who were randomized into the study later and participated for a shorter time period, obscured the prophylaxis of depression we have reported here (22). This suggests that it may take a longer time to demonstrate lithium prophylaxis in bipolar II than in bipolar I patients, since lithium was shown to be equal to placebo when data from patients who had been studied for shorter periods were added.

Our data also indicate that lithium has a prophylactic effect in unipolar recurrent depression. There were fewer and less severe episodes and fewer dropouts in the lithium-treated unipolar group. We have previously reported results favoring lithium over placebo in the treatment of recurrent depressions, as have several other groups (9, 10, 11, 17, 23). Prien and associates (23) demonstrated the equal efficacy of lithium and imipramine as compared to placebo through a significant reduction in affective episodes among 78 unipolar patients randomly assigned to lithium, imipramine, or placebo. Klerman and associates (24) and Mindham and associates (25) have also shown depression prophylaxis with tricyclic antidepressants. Tricyclics combined with maintenance lithium therapy may be superior to either lithium or tricyclics alone in the overall group of unipolar patients. It is also possible that there are subtypes of unipolar depression which would do better if treated with lithium alone or antidepressants alone.

Our findings point to the value of employing multiple indices of prophylaxis in ongoing studies of recurrent illnesses. When the cutoff points for termination of episodes are not delineated through follow-up, placebo dropout rates and duration of episodes may appear as false negatives when other analyses show positive results. In such instances, the length of regular attendance in the clinic and the relative time that patients are normothymic are often more reliable indices of prophylaxis than dropout rates and duration of the depressive episodes. Patients are considered to be survivors if they have not dropped out or been hospitalized during the course of the study, despite mild to moderate depressions or hypomanic episodes. The time these people survive, i.e., remain in the study, constitutes another "benefit" index of prophylaxis, as can be seen in our data for bipolar II patients. In our study, duration of attendance was longer in lithium-treated groups for each subtype.

There may also be false positives in the dropout and hospitalization rates for depression. For example, patients who believe they benefit from clinic attendance and from the medication they are receiving may actively attend the clinic during episodes, while those who feel they do not benefit may drop out and be unavailable for depression ratings. We hope that such patients occur in equal proportions in the randomized lithium and placebo groups.

In summary, our data indicate lithium prophylaxis of depression on multiple indices in bipolar I, bipolar II, and unipolar patients. However, additional studies of lithium prophylaxis are needed, particularly in relation to tricyclic medication, since millions of cyclically depressed people are now being considered as candidates for maintenance drug therapy, which is the real psychopharmacological revolution in psychiatry.

Alcohol and Drug Abuse Consultation in the General Hospital: A Systems Approach

BY MARC GALANTER, M.D., TOKSOZ B. KARASU, M.D., AND JACK F. WILDER, M.D.

The authors describe a program that is directed at assuring effective treatment and referral for alcoholic and addicted patients in a general hospital; the program was developed to assure maximal utilization of available addiction treatment facilities without adding to the hospital staff. Drawing on systems theory, the authors review both a pragmatic and a conceptual basis for psychiatric intervention with paraprofessional support to provide consultation to the general medical staff who treat alcoholic and addicted patients. They stress the feasibility of altering the nature of the hospital system to achieve more effective treatment for these patients.

THIS REPORT PRESENTS an approach to providing alcoholism and drug abuse consultation services to a general hospital. It draws on our experience in establishing such a service for the Bronx Municipal Hospital Center, the principal teaching hospital of the Albert Einstein College of Medicine. The perceived need for this program arose from the experiences of the hospital staff in their respective services. Many alcoholic and addicted patients were found to be uncooperative with medical regimens; they often disrupted hospital routines. Effective assistance was needed for the management of drug-abusing patients while they underwent medical treatment in the hospital. A committee of the medical board of the hospital was therefore established to initiate a program to answer this need. We describe the approach we developed because it may serve as a model for similar work in related contexts.

The authors are with the Albert Einstein College of Medicine, 1300 Morris Park Ave., Bronx, N.Y. 10461. Dr. Galanter is Assistant Professor and Career Teacher in Drug Abuse and Alcoholism; Dr. Karasu is Director of Psychiatry, Albert Einstein College of Medicine-Bronx Municipal Hospital Center; and Dr. Wilder is Associate Dean for Operations.

This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grant D20-MH-00851 from the National Institute of Mental Health.

Drs. R. Steinmuller, J. Lowinson, and E. Sachar of the Albert Einstein College of Medicine; Ms. F.L. Nurnberg; and R. Rosso and B. Moy of the Addiction Services Agency of New York, N.Y., assisted in this project.

THE HOSPITAL AND ITS DISTRICT

The hospital serves a district in the northeast Bronx with a population of 423,000. The neighborhoods in this district range from single-residence upper-middle-class areas to lower-class public housing areas, with some slums characterized by tenement housing. Although the overall population is three-quarters white, certain areas of the district are two-thirds black and Puerto Rican. Patients from these areas, as well as substantial numbers of patients transferred from emergency services adjacent to the hospital's catchment district, yielded a disproportionately large percentage of addicted and alcoholic patients at the hospital.

Some 25,000 patients are treated annually on the inpatient services; 45,000 patients are treated annually in the emergency rooms. An unpublished survey of the hospital showed that 5.1% of the inpatients and 2.1% of the emergency patients were apparently addicted to or abusing drugs. Another unpublished survey of the medical wards showed that 21% of the patients were alcoholic, a figure similar to that reported in the literature (1).

In our discussions with members of the medical, nursing, and social service departments, it became apparent that little special attention was being given to the treatment of the addictive problems of these patients, although a great deal of staff effort was invested in treating their medical problems, usually the sequelae of alcoholism or addiction. In addition, the addictions were not quite considered medical illnesses; rather, they were considered "social diseases," and "dirty" ones at that. Because of this, we decided that the hospital staff were as important as the addicted patients as a target for our program. In this regard, it became useful to conceptualize an approach to this issue in terms of systems theory.

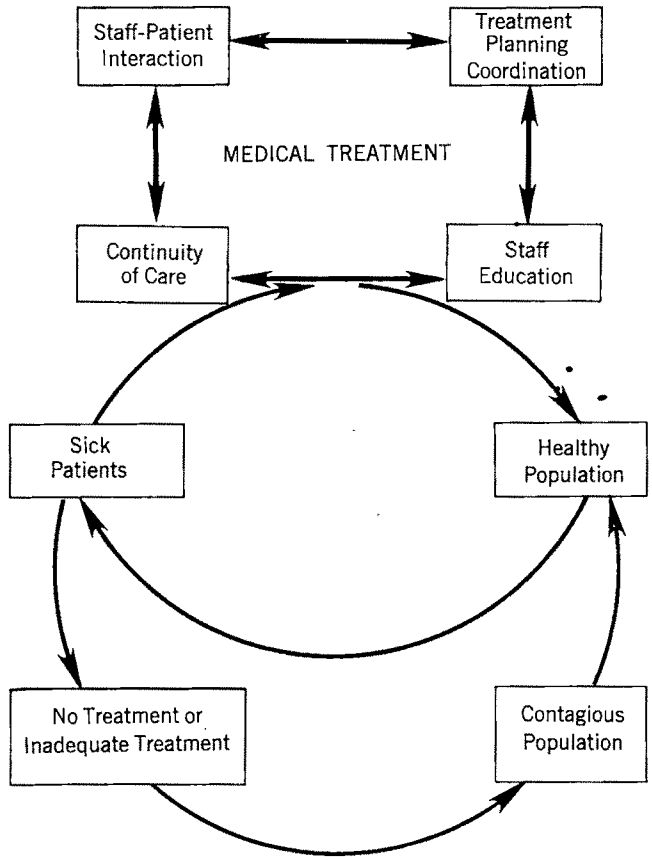
A SYSTEMS APPROACH

Systems theory was developed by Ludwig von Bertalanffy (2) as an approach to the study of interactions among related functional entities. These entities and the relationships among them constitute a system. Closed systems are those which are considered in isolation from their environment. Open systems take into

account the effect of interactions with the environment as well as internal variations. It is therefore possible to isolate a particular process and represent it as a closed system. However, this may not adequately represent the full complement of forces that are in operation. For a more valid representation, the systems may require analysis in relation to the external forces operating on it, i.e., as an open system.

In studying mental health service delivery, this approach has been used in the analysis of attitudinal and administrative issues affecting the interaction of an acute psychiatric service in a general hospital with a state-hospital-based long-term psychiatric treatment facility (3). By applying computer simulation techniques, means of minimizing patient dropout have been studied within the context of a community mental health center (4). Similar computer simulations have been used in the field of addiction to predict the effect of various treatment modalities and control operations on heroin distribution patterns within a defined community (5) and to analyze the cost-effectiveness of various addiction treatment strategies (6).

We adopted this approach in addressing the following questions: What factors eventuate in the limited attention paid to the primary medical problem of alcohol and/or drug abuse within the context of a medically sophisticated hospital setting? What means would be most efficient in facilitating effective treatment for these patients? We began by viewing the hospital-based treatment of the medically ill as a system.



The most frequently used model of medical treatment can be conceptualized as a closed system. This model may be applied to treatment of a disease such as appendicitis. Because the factors one considers in the treatment of such an illness can be limited to direct medical intervention, the system may be viewed as a closed one: the medically ill are admitted to the hospital, receive treatment, and then rejoin the healthy population.

This model of medical care was being applied at the hospital to the treatment of addicted and alcoholic patients at the time intervention was requested. Direct treatment was given only for the medical sequelae of addiction. These sequelae were regarded as if they were the primary disease process. After the acute medical difficulties were resolved, patients were at most given the name of a drug treatment program to contact. The possibility of the hospital staff's active involvement in the patients' alcohol or drug problems was not considered a part of this closed medical treatment system, and the issue of drug or alcohol abuse treatment per se was not seen as related to the operations of the general hospital. In our opinion, this model was intimately related to the management problems the staff experienced in working with alcoholic and addicted patients.

A second model of medical care is generally applied in the case of infectious diseases in order to deal with factors that directly affect the natural history of transmitted illness. If the closed system of the initial treatment model were applied, medical intervention would be directed solely toward infected patients. Such treatment would be inadequate because the potential for spread of the disease requires consideration of the medical system in relation to its environment, that is, as an open system. This introduces issues such as quarantine into the medical treatment system to prevent disruption of function within the hospital system. If this model were applied to addicted and alcoholic patients, however, they would be treated in isolation from other patients, perhaps on a separate medical service. This would perpetuate the exclusion of addictions from consideration as medical illnesses that merit treatment and would fail to deal with the social factors that lead to "reinfection" outside the hospital and to patients' reluctance to seek help for their addictive illnesses.

We concluded that effective intervention required the examination of a subsystem within the models just described—that a third, "social disease" model had to be used (see figure 1). Medical treatment could not be presumed to be a distinct entity in the case of such "social diseases" as addiction and alcoholism. It must be viewed as a complex subsystem that interacts with its own environment so that the operations of one affect the definition of the other.

FIGURE 1
The "Social Disease" Systems Model

Within the subsystem of medical treatment, the following areas required examination: 1) staff-patient communication, 2) coordination of treatment planning, 3) continuity of care, and 4) staff education. These four factors were seen to be relevant to the very nature of what was defined as medical treatment in this third model and will be described below. A consultation service for alcoholic and addicted patients should be designed to intervene in these four areas to assure that the investment of effort will yield success. By these means, the problems of drug abuse and alcoholism in the hospital would be redefined so that the medical management of the alcoholic or addicted patient would include consideration of the primary problem of addiction as well as its sequelae.

THE CONSULTATION SERVICE

A service was established to provide consultation for patients with drug abuse problems while they were receiving general medical treatment; its existence was publicized at the hospital. The staff of the consultation service included a psychiatric director (M.G.) and three counselors, two of whom were ex-addicts. When a request for consultation was received, a counselor was sent to assess the clinical situation. After a review of the case and consultation with the ward's medical staff, plans were formulated regarding ward management and, when appropriate, referral to long-term treatment.

Emphasis was also placed on training exercises for the medical, nursing, and social work staffs of the hospital. At scheduled sessions, consultation service members made presentations related to alcohol and drug abuse that were appropriate to the audience. These presentations were made in such contexts as medical grand rounds, emergency room staff meetings, and social service conferences.

During the first 15 months of operation of the program, 950 patients were seen. Table 1 indicates the service of origin of patients for whom consultation was requested. The emergency rooms were responsible for about one-third of the consultations because they deal with the immediate results of drug overdose and intoxication as well as many sequelae of alcoholism and addiction. The medical and surgical services also yielded a large proportion of the referrals because of the frequency of hospitalization for overdose, alcoholic gastrointestinal disease, major trauma, and multiple abscesses. Cases of opiate addiction on the obstetrics service were often identified because of withdrawal symptoms in the newborn.

The psychiatry wards, which house over 10% of the beds in the hospital center, contributed only 2% of the referrals for consultation. This probably reflects the fact that many problems seen by psychiatrists as principally psychiatric actually develop secondarily to a primary difficulty of drug or alcohol abuse, often unattended to by the psychiatrist (7). However, in the psychiatric emergency room, where the search for rapid disposition other than psychiatric hospitalization is often the goal with alcohol- or drug-abusing patients, the services of the consultation staff were more frequently sought.

TABLE 1
Referrals for Consultation for 950 Patients, by Service That Referred Them

Hospital Service	Patients Referred	
	Number	Percent

Total	222	37
Alcoholism treatment		
Detoxification	164	28
Outpatient therapy	200	34
Total	364	61
Other	10	2

Of 876 patients for whom consultations were made in 1974, 596 (two-thirds) were referred for treatment of alcoholism or drug abuse before their discharge, as indicated in table 2. Follow-up revealed that 449 (three-quarters) of those referred appeared for treatment within 1 week of the referral. Given the general reluctance of addicted patients to participate in treatment, as well as the mutual distrust generally experienced between such patients and hospital staff, this represents an appreciable rate of success in our opinion.

CASE REPORTS AND DISCUSSION

The following vignettes are given to illustrate the role of the consultation service within the hospital sys-

tem with specific regard to the four areas of medical management noted to bear on the "social disease" systems model.

Staff-Patient Interaction

Case 1. A 35-year-old unemployed man on methadone maintenance who lived with his parents was admitted to the surgical service with stab wounds incurred in a street fight. Consultation was requested when the patient, who had previously been uncooperative with medical routines, was found to be using barbiturates brought in by visitors. When interviewed by the counselor the patient admitted that he had been discharged from two methadone programs during the past 2 years because of barbiturate abuse; he anticipated a similar outcome at his current program. The patient's status was reviewed, and a schedule for barbiturate detoxification was established. The drug abuse counselor saw him daily, and he became more cooperative. Discussions with the patient often centered around his opportunity to enter a drug treatment program that incorporated both residential treatment and methadone maintenance. The patient entered this program on discharge from the hospital.

As is often the case with addicted patients, the ward staff and this patient became polarized in a hostile interaction. At such times the patient is seen by the staff as a culprit who undermines their attempts to make the medical regimen effective. He then serves as a scapegoat for a variety of staff frustrations, many of which stem from their own feelings of guilt and helplessness in the many clinical situations in which their concerted treatment has limited success. The patient, habituated to violating norms of behavior, suppresses his own understanding of the anger he may arouse. He has in the past precipitated rejections by helping agents and approaches the ward situation with little hope that his problem with drug abuse will be accommodated.

The counselors, who are called from outside the immediate ward system, arrive without commitment to either of the "combatants." They have had experience and training in working with addicts and in eliciting a history of drug abuse, and they are seen by the patient as a step removed from the medical hierarchy. These factors make it easier to ascertain the specifics of the patient's drug abuse history. In addition, because they are trusted by the ward staff, counselors help to defuse an explosive situation and may markedly improve the pattern of interaction between patient and staff.

Coordinated Treatment Planning

Case 2. A 24-year-old single woman was hospitalized for hepatic complications of alcoholism. She had started to drink heavily after her common-law husband left her a year before and she moved in with a relative who was an alcoholic. The patient was at first adamant in refusing treatment for her alcoholism. During the course of her hospitalization, however, the counselor maintained regular contact with her while the ward social worker began seeing her mother. Two meetings were held with all four parties and the ward physician. The patient ultimately accepted referral to a residential setting for alcoholic and drug-abusing patients.

Many treatment agents operate within the hospital complex and, although each may deal directly with the patient, their efforts are often not coordinated. This is particularly true with the alcoholic or drug-abusing patient, whose physicians, social workers, and nurses may relate to different facets of a complex social issue. In this case, the availability of a single person who worked to facilitate communication within the treatment subsystem was valuable. The presumption of effective coordination of all those treatment entities which act on the "sick patients" in our systems approach (see figure 1) cannot be made without a carefully coordinated treatment plan.

We attempt to enlist the assistance of the ward staff in disposition planning, making use of the specialized knowledge they may provide. This also serves to educate the staff regarding the issues involved in drug abuse treatment. As they become aware of management options that were not previously apparent, the ward physician and social worker begin to view the addicted patient as one who presents problems that may have solutions. This contributes to undercutting the frustration and consequent resentment that has previously been more typical of their response.

Continuity of Care

Case 3. A 16-year-old high school student was referred by the psychiatric outpatient department to the psychiatric emergency service. She had been brought there by her mother because of many arguments between her and her parents, most of which centered around her association with a group of friends involved with drugs and alcohol. During the interview the counselor ascertained that she had been regularly abusing barbiturates and wine for 2 years. When she was first evaluated and then seen on two subsequent visits, she was unwilling to enter a long-term therapeutic program. As is the usual practice, however, the counselor made it clear that he would be available if she wanted help in the future. Two months later the patient contacted the consultation service herself. After further sessions, referral was made to an ambulatory therapeutic program for adolescent drug abusers.

Continuity of care is a goal that is often elusive within the context of a large hospital. This is particularly true for the drug-abusing patient because of his or her role as renegade within the treatment system. Multimodality services that are integrated into the fabric of the medical treatment system are maintained for such complex illnesses as renal disease and infectious disease. Similar services would assure continuity of care for the drug-abusing patient as well. This would militate against shuttling the abuser from one hospital department to another, as occurred with this patient, who had been sent from the outpatient department to the emergency room, and also facilitates the patient's returning to a consultation context with a familiar staff. In addition, the counselors, who have a more extensive knowledge of the many agencies to which they may refer addicted patients, can assure more flexibility in choosing a program especially suitable for a particular patient. The original referring service then

comes to see such patients as ones whose difficult problems may be dealt with by a more sophisticated approach rather than as patients whose problems are unsolvable.

Staff Education

Some situations warrant systematic intervention with a larger group of staff. This was our experience on the postpartum ward and newborn nursery. The consultation service was contacted by the nursing supervisor for these units after a number of arguments had arisen between the nursing staff and addicted women who were admitted for delivery. One call was precipitated by an incident in which a patient struck a nurse's aide in the newborn nursery. This patient had angrily insisted on seeing her child at a time that conflicted with ward regulations, and the aide, in angry response, had called the mother a "junkie who was killing her child."

After consulting with the head nurse and a number of staff members, we decided to conduct a series of eight weekly meetings with the nursing staff that embodied a variety of didactic approaches. At some of the sessions nursing staff members were encouraged to ventilate their feelings regarding the addicted patients, many of whom presented difficult management problems. Techniques for management were discussed. In one session a film was shown of a nurse working with an addicted patient in a hospital setting. Two sessions were devoted to conveying specific information regarding the history and pharmacology of drug and alcohol abuse.

Staff members were often defensive about their own hostility toward addicted patients, and special care was taken to avoid accusatory behavior that might elicit further defensiveness. This issue was particularly relevant for the obstetrics service: the nursery staff, often with ample justification, saw themselves as protectors of helpless infants whose lives were threatened by addicted mothers. It was important that the nurse's sense of frustration and anger be given open expression at these meetings so that it might be dealt with constructively.

COMMENT

The program outlined in this paper represents an effort at intervention in the hospital as a treatment system, directed principally at the redefinition of what is considered medical treatment of the addicted or alcoholic patient. Because the interventions described here are made at a time when contact between the caregiving community and the addict is premised on the offering of patently helpful medical assistance, a unique opportunity exists for establishing an alliance with such patients. The consultation service is oriented toward altering the views of both the hospital staff and the alcoholic or addicted general medical patient. It thereby becomes a vehicle for assuring that actors in the "social disease" system will come to view addiction as a treatable illness rather than as an encumbrance to the legitimate medical routine.

Competency-Based Psychiatric Education

BY HARVEY M. WEINSTEIN, M.D., AND MICHAEL L. RUSSELL, PH.D.

The focus of training in a competency-based residency program is on ensuring that all residents attain prespecified levels of competence for particular objectives in each training activity. The authors examine the components of a competency-based program and describe the phases of development that their department went through in creating such a program. They conclude that the competency-based training model directly faces the issue of certifying competence by holding itself accountable in a demonstrable way for ensuring that its residents have mastered specific areas of knowledge, skills, and attitudes.

DURING THE PAST FEW YEARS residency training programs in psychiatry have come under increasing scrutiny by those within and outside the medical profession. In this era of increasing consumerism and government participation in all levels of health care, psychiatry is being called on to reassess its certification procedures, establish peer review mechanisms, and justify training costs. In response to these demands there are continuing debates surrounding issues in residency education (1–7), such as defining a core curriculum, establishing a first postgraduate (internship) year, and teaching personal development or somatic therapies.

It is our contention that many of these current issues are symptomatic of a deeper, more fundamental problem in residency education. To date, psychiatry has not clearly defined the skills, knowledge, and attitudes that the psychiatrist-in-training must demonstrate in order to be certified as competent (8, 9). It is our belief that the profession can no longer avoid beginning the difficult, often emotion-laden task of specifying what a psychiatrist should know and be able to do.

Although we may not yet be able to understand or even accurately describe much of what occurs in the therapeutic process, most clinicians would agree that there are many areas that can be identified as central to the training of any psychiatrist, regardless of theoretical framework. It is only after these areas have been clearly identified that the educational issues of length or format of training can be addressed. Once we have described the knowledge, skills, and attitudes that we expect our residents to learn, a variety of paths by which a resident masters these skills can be developed. Equally important, having prespecified criterion levels for performance, assessment procedures can be established for both evaluation of learning and evaluation of competence (10). Once the acquisition of core skills can be objectively measured, a residency training program can be individually tailored for the resident.

The following example illustrates how a resident would proceed through training in crisis intervention if training were approached from this perspective.

> Dr. X enters the first year of the residency program on July 1. During the first week, he completes a series of exercises in all areas of training offered in the department. One of these tests is a written exercise based on the stated behavioral objectives for training in theory and techniques of crisis treatment. If the resident successfully demonstrates that he knows crisis theory and can apply it in a clinical setting under the supervision of a faculty member (i.e., evaluate, diagnose, and appropriately manage a suicidal patient), he may be excused from the seminar on crisis treatment and the crisis clinic rotation. If he cannot demonstrate this knowledge and the requisite skills, he attends the seminar and completes the rotation.
>
> At the end of the rotation and seminar, the resident is retested. If he is unsuccessful in demonstrating his mastery of crisis theory and practice at this time, he may elect a tutorial, spend extra time on the crisis clinic rotation, seek additional readings, or review demonstration videotapes. Throughout the training program he is afforded ample time and various options to acquire the specified competencies. Once he has successfully demonstrated mastery of crisis treatment, he turns his attention to working on other areas.

With this example in mind, we will examine the components of a competency-based residency program. In addition, we will describe the phases of development of such a program that we experienced in the Department of Psychological and Social Medicine of Pacific Medical Center.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

At the time this paper was written, Dr. Weinstein was Director of Training and Dr. Russell was Director of Educational Research, Department of Psychological and Social Medicine, Pacific Medical Center, San Francisco, Calif. Dr. Weinstein is now Assistant Chief of Psychiatry, Veterans Administration Hospital, San Francisco, Calif. 94121, and Dr. Russell is Assistant Professor, Department of Community Medicine, Baylor College of Medicine, Houston, Tex.

COMPETENCY-BASED LEARNING

A competency-based training program (11–13) differs from traditional psychiatric residency programs. The standard educational practice in residency programs has been to preset the length of time allowed for each training activity (e.g., a 12-week seminar or a 6-month rotation) and to define only vaguely the objectives for the activities. As a result, the resident emerges from a residency having gained varying degrees of competence in a number of areas undifferentiated as to their importance. In a competency-based residency, however, the focus of training is on ensuring that all residents attain prespecified levels of competence for particular objectives in each training activity. The time for completion of training is allowed to vary for the individual resident within the 3-year period specified by the American Board of Psychiatry and Neurology.

Phase 1: Core Areas

The competency-based program has been built on a framework of core areas and optional areas (14). These concepts provide a broad behavioral description of the knowledge and abilities each resident is expected to acquire from departmental teaching activities. The descriptions have been in continuous development by an interdisciplinary team of mental health professionals (psychiatrists, psychologists, and social workers) and the residents in the program. The core area descriptions represent a commitment by the department to delineate what the faculty consider necessary for the resident to learn before completion of the residency. The process of developing core areas involves hours of deliberation and debate by the faculty. Once agreed upon, these areas provide the structure on which the program is based. The faculty understand that these descriptions represent a consensus of what the department currently accepts as essential for the practicing psychiatrist and also recognize that these areas may be modified by experience and feedback.

The core area descriptions have been written in broad terms to serve as a general outline within which the department can focus training. These goals are guidelines to be used by individual faculty members in the creation of specific performance objectives for clinical rotations and instructional activities. The general areas covered in these descriptions include the following: diagnostic knowledge and skills, social management, fundamental theories of behavior, treatment knowledge and skills, somatic management, legal management, treatment monitoring, breadth of treatment experience, community psychiatry, personal and professional growth, and related professional skills (see appendix 1).

In the process of creating these core areas a series of optional areas also emerged. While pursuing mastery of the skills and knowledge areas specified for each of the core descriptions, a resident has the opportunity to acquire additional training in any of the optional tracks: research competencies, teaching, administration, and advanced training in such specialty areas as child psychiatry, behavior therapy, and consultation. The resident works with a faculty member who acts as program adviser to determine which of the core or optional areas will be covered in each stage of his or her professional development. An individual program is therefore tailored to the resident's own professional or personal goals.

In developing the residency program we have had to work from the broad goals outlined in the core area descriptions to behaviorally referenced performance objectives (15). This approach has enabled us to reorient the faculty to view the residency training program in terms of skills and knowledge that can be expressed specifically as performance objectives rather than in the broad terminology of a core curriculum. These performance objectives specify the extent to which the resident must perform a specific behavior in a particular setting to demonstrate mastery of the ability. In other words, the performance objectives clearly define the required behavior of the resident; the quality of the resident's performance in terms of strength, duration, or frequency; and the social or physical conditions under which the behavior must be performed.

Performance objectives have been grouped under three headings: knowledge (what the resident needs to know), skills (what the resident should be able to do), and attitudes (the personal characteristics that the resident should develop). The process of education then involves the development of learning objectives in these three areas. Every teacher and supervisor in this program participates in developing specific objectives for whatever aspect of the program for which he or she has responsibility. These objectives must be related to a core or optional area that the faculty as a whole has previously identified.

As the performance objectives for each instructional activity are determined before the resident begins the training experience, the faculty member's role in training becomes that of facilitator, helping the resident master the stated objectives. The resident and the instructor/supervisor become partners in the learning process. The competency-based system of training therefore makes certain that the learners and teachers are clearly aware of the goals of the training (i.e., they know what is to be evaluated and, because these goals are described behaviorally, how they will be measured). As George Miller (16) said, "The final test lies not in what . . . [the student] was taught, but in what . . . [the student] does."

Phase 2: Instructional Steps

Once the performance objectives for the instructional activity have been identified, the nature of the instruction that will be used to teach them must be determined (see appendix 2). In most cases, instructors have tended to build their seminars and clinical rotations around clusters of learning modules. Each learning module focuses on a specific topic and is composed

of a series of performance objectives.

The learning modules are designed to be as self-contained as possible. All of the materials needed to master the performance objectives are presented or available within the module. This unique feature of the instructional activities allows the resident to select from a course of instruction the specific modules that teach the skills he needs to acquire. As the learning modules develop, the faculty identify a variety of presentations of the material. These may include audiovisual presentations from past seminars, recordings of work with patients that illustrate particular skills, role-play demonstrations of technique, and the assignment of relevant literature to read. Eventually many alternative methods of presenting the same material become available to the resident. These materials can be selected to meet the individual resident's own style and rate of learning. In this way, if the resident does not master a particular competency on the initial presentation, a variety of methods continue to be available to him or her to help develop mastery. Such an approach differs from the practice found in many psychiatric residencies of offering the resident only a single path for acquiring competence in a given area.

Phase 3: Assessment

Unlike most norm-referenced evaluation systems, in which the resident is compared with other students in the same group and given a relative evaluation, assessment in a competency-based training program is criterion-referenced and specific to the resident. That is, the resident's abilities are evaluated in relation to a prespecified set of behaviors. Because the performance objectives have been clearly specified for each instructional activity, the task of evaluation becomes a straightforward determination of whether or not the resident has demonstrated a particular behavior according to a given standard under the prescribed conditions. If the resident does not demonstrate mastery, he or she returns to practice the skill and is reevaluated at a later time.

The evaluation of the resident's skill occurs at three different points in the acquisition of the skill. Before each seminar and clinical rotation the resident is offered the opportunity to demonstrate his or her mastery of the skills and knowledge to be taught in the instructional activity. This procedure allows the resident to bypass training activities that are unnecessary for him or her and to proceed to other experiences. Increased faculty time and effort can then be spent with residents who have yet to master the specific performance objectives concerned.

The second evaluation occurs at the completion of each training activity. In this evaluation the resident demonstrates the skill immediately after its acquisition. That is, the skill is learned, practiced, and evaluated by itself. This type of evaluation occurs on completion of a seminar or rotation.

The third type of evaluation is scheduled every 6 months. In this evaluation the skills of the resident are assessed in combination, as they would be used in clinical practice. This formal cumulative evaluation requires the resident to demonstrate his or her complete therapeutic repertoire and knowledge base as a functioning clinician. It ensures that the skills the resident demonstrated during each of the seminars and clinical rotations have been retained. Recently this took the form of "treating" a simulated patient as she moved from initial presentation at a crisis clinic to an inpatient unit to a halfway house and finally into outpatient therapy. Through a combination of paper and pencil examinations and live interviews with a simulated patient, all of the performance objectives covered in the clinical rotations and department seminars offered during the previous 6 months were evaluated. In addition, each interview was rated according to objective criteria to evaluate interview skills. The interviews were videotaped and rated by the faculty. The results were then reviewed with the resident.

These taped interviews can also be used for comparison with subsequent interviews performed in later evaluations. Areas in which the resident would benefit from further training are also identified so that the resident will attain mastery of these in the succeeding 6-month period.

In summary, assessment in a competency-based training program requires the determination of whether a resident has successfully mastered the prespecified performance objectives. Although we have directed our initial efforts toward developing reliable and valid instruments to do this, we also recognize that this process requires a continual review of the original performance objectives. The faculty evaluator must answer not only the question, Has this resident demonstrated mastery of these performance objectives? but also the question, Should these performance objectives be accepted as indicators for mastery of the core area material? Development of assessment methodology in a competency-based program requires a critical eye on both of these issues.

IMPLICATIONS OF THE PROGRAM

A direct result of our competency-based model for training is that as faculty members have specified the performance objectives taught in their seminars and clinical rotations, areas of overlap have become clarified. In several areas, needless repetition of instruction has been eliminated and a concerted effort has been made to develop a complementary relationship among the instructional activities. A coordinated training program in which knowledge is taught in one setting and applied and evaluated in another is gradually emerging. The program is beginning to confront the frequently heard lament of the resident that training in psychiatry lacks cohesiveness and congruence.

We have found that a major consequence of developing this model of psychiatric residency education is that our training program is directly facing the issue of

certifying the competence of its graduates. The program is holding itself accountable in a demonstrable way for ensuring that its residents have mastered very specific areas of knowledge, skills, and attitudes. One of the byproducts of this educational model is that the student is trained to objectively scrutinize his or her learning needs, develop ways of meeting these needs, and evaluate his or her success in acquiring the needed abilities. The resident becomes responsible for sharing in the development of his or her education as well as evaluating how he or she is learning. A process is established that we hope will promote the continuing education of the psychiatrist.

It appears to us that the competency-based educational model also has important implications for the national certification process. If therapeutic skills and knowledge areas can be objectively identified and agreed on, the potential exists for focusing certification by a regulatory body on these performance objectives. Such a certification process would be criterion-referenced (i.e., based on stated preset minimum levels of competency of which every candidate for certification would be aware before the evaluation) and would require the candidate to demonstrate competency for abilities mastered in his or her own training program.

With the increasing demand on our profession to justify our skills, treatments, and costs, the possibility now exists for us to teach and certify our abilities as mental health professionals in a way that has heretofore not been possible.

APPENDIX 1
Sample Core Areas

DIAGNOSTIC KNOWLEDGE AND SKILLS

The mental health professional, given a particular patient, demonstrates the ability 1) to perform a complete mental status examination and 2) to differentiate between descriptions of various behaviors and inferences based on such descriptions.

FUNDAMENTAL THEORIES OF BEHAVIOR

Developmental Theory

The mental health professional can describe various developmental theories concerning the patterns of behavior over the life span, noting the specific developmental tasks for infancy, childhood, adolescence, early adulthood, maturity, old age, and dying.

Biological Theory

The mental health professional can describe current concepts and research data concerning the role that genetic endowment plays in the genesis of the following illnesses: schizophrenia, affective disorders, and alcoholism.

TREATMENT KNOWLEDGE AND SKILLS: THE INTERVIEW

The mental health professional, having established a therapeutic contract with its general agreement as to goals, demonstrates certain necessary interview skills, as follows: given a particular patient, demonstrates that when appropriate, he or she can 1) in the initial interview, establish that degree of rapport which leads to the patient's return and 2) "modify the therapeutic approach," that is, make changes in his or her overt behavior when indicated as agreed upon by therapist, supervisor, and patient.

APPENDIX 2
The Competency-Based Model As Applied to a Seminar in Emergency Psychiatry

CORE AREA: FUNDAMENTAL THEORIES OF BEHAVIOR: CRISIS THEORY

The mental health professional can 1) describe the ways in which a social network a) contributes to crisis development and b) contributes to crisis resolution; 2) describe the emergency psychotherapist's work in terms of various techniques that distinguish emergency psychotherapy from other types of psychotherapy (e.g., crisis interviewing, environmental manipulation, decision counseling).

Performance Objectives

1. Given two different instances of a patient in crisis, the mental health professional can a) describe and define the concept of ecological group, b) name the members of the patient's ecological group, c) discuss the patient's crisis in terms of the pressures (strain) registered throughout the entire ecological group at the time, and d) identify other potential victims of crisis in the group.

2. Given two instances of an acutely suicidal patient in the emergency room, the mental health professional can a) evaluate the suicidal risk, b) identify the immobilization response in significant others, c) suggest possible lifelines, d) state when hospitalization is the appropriate management, and e) state when involuntary hospitalization is the appropriate management.

Instructional Activities

1. Seminar in Crisis Theory

The first performance objective described above will be discussed in two one-hour seminar sessions. The residents will review a chapter of the instructor's book dealing with principles of crisis intervention.

For the second performance objective the five evaluation procedures for dealing with the acutely suicidal patient will be discussed in three one-hour seminar sessions. Two articles discussing the theory and use for each procedure will be distributed. In one session, a videotape will be played illustrating how an experienced therapist employs each procedure with a simulated patient in crisis.

2. Clinical Rotation: Emergency Room

Each resident will be on call for psychiatric emergencies in the emergency room at least one evening a week throughout two years of the residency program. He or she will also spend six weeks in a crisis clinic.

The resident must successfully accomplish both of the following: 1) the resident completes a written posttest (exercise) at the end of the seminar sequence that allows the resident to demonstrate mastery of the performance objectives for hypothetical patients in crisis; 2) the resident presents to his emergency room supervisor two cases of acutely suicidal patients seen in the emergency room and describes how he or she employed each procedure with each patient.

Alternate Teaching Sequence

If the resident does not master the performance objectives, the faculty member will direct the resident to one or more of the following: 1) viewing of additional videotape(s) of an experienced therapist working with crisis situations, 2) reading literature that discusses these techniques, 3) listening to an audiotape of the faculty discussing these procedures, and 4) assignment to the emergency service for an additional six weeks with a tutor.

Amantadine Versus Trihexyphenidyl in the Treatment of Neuroleptic-Induced Parkinsonism

BY WILLIAM E. FANN, M.D., AND C. RAYMOND LAKE, M.D., PH.D.

Amantadine is a putative dopaminergic compound known to be therapeutically effective in idiopathic and postencephalitic Parkinson's disease. In a double-blind placebo-controlled crossover study of 39 psychiatric inpatients, amantadine and trihexyphenidyl were equally effective in treating drug-induced parkinsonism, and amantadine produced fewer and less severe side effects. The authors suggest that amantadine is an effective alternative to atropine-like agents, with fewer implications for long-term risk of tardive dyskinesia.

THE PARKINSONIAN-LIKE neurotoxic side effects of neuroleptic compounds have been recognized since the introduction of chlorpromazine in the early 1950s. Since drug-induced parkinsonism is symptomatically equivalent to the idiopathic or postencephalitic types of Parkinson's disease, clinicians have reasoned that the atropine-like antiparkinsonian agents that are effective in the treatment of Parkinson's disease might also reverse the drug-induced phenomena. This clinical supposition has been proven by broad experience to be substantially correct, and it has become standard practice to prescribe antiparkinsonian agents prophylactically at the outset of neuroleptic therapy.

However, recent evidence indicates that these atropine-like agents may increase the patient's risk of developing tardive dyskinesia, and some clinicians are now prescribing antiparkinsonian agents only after the patient develops symptoms of extrapyramidal neuroleptic side effects, rather than prophylactically (1, 2). Furthermore, there is growing agreement that the antiparkinsonian compounds should be discontinued after a very limited period of time and the patient reevaluated for recurrence of parkinsonian symptoms (3).

Dr. Fann is Professor of Psychiatry and Associate Professor of Pharmacology, Baylor College of Medicine, Texas Medical Center, Houston, Tex. 77025. Dr. Lake is Research Associate, Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, Md.

This work was supported in part by E.I. Du Pont de Nemours & Co., Wilmington, Del., and by a grant from the Veterans Administration.

Amantadine and trihexyphenidyl were supplied by Marvin Paulshock, Ph.D., of E.I. Du Pont de Nemours & Co. The authors also wish to acknowledge the assistance of Bruce W. Richman and Jeanine C. Wheless in conducting the study and of Nancy Berry in the preparation of the manuscript.

An additional consideration in the prescription of antiparkinsonian medication for drug-induced symptoms is the possibility that these atropine-like agents create or aggravate a hypocholinergic state through long-term suppression of those striatal neuronal systems dependent upon acetylcholine as a transmitter agent (4). Because all but two of the currently available antiparkinsonian agents are atropine-like (i.e., antagonize striatal acetylcholine function), we chose to explore the possibility that restoration of the dopamine-acetylcholine balance in the striatum could be accomplished through the use of a compound that enhanced striatal dopamine activity rather than blocking acetylcholine. Amantadine hydrochloride is a compound without anticholinergic effects that putatively acts to enhance central nervous system dopamine (5–8). It has been therapeutically effective in idiopathic and postencephalitic Parkinson's disease and is commonly prescribed for treatment of these conditions (9). It was our intention to test the compound's effectiveness in drug-induced parkinsonism as an alternative pharmacological approach to treatment with fewer implications for long-term risk.

METHOD

Subjects

Forty-one patients from two psychiatric institutions were accepted for the study after clinical examination and diagnosis of drug-induced parkinsonism. Informed consent was obtained from each patient after the nature of the experiment was fully explained. The history and medical and psychiatric records of each patient showed no indication of preexisting idiopathic or postencephalitic Parkinson's disease. All subjects had developed drug-induced extrapyramidal symptoms during treatment with antipsychotic medication for the following disorders: schizophrenia, chronic undifferentiated type (N=20); schizophrenia, chronic paranoid type (N=7); schizophrenia, schizo-affective type (N=5); schizophrenia, hebephrenic type (N=1); schizophrenia, catatonic type (N=1); schizophrenia, type undetermined (N=2); senile psychosis (N=2); manic-depressive psychosis (N=1); postpartum psychosis (N=1); and chronic organic brain syndrome associated with syphilis (N=1). Pregnant women and patients with hypersensitivity to antiparkinsonian or stimulant agents were excluded.

Each subject was evaluated by means of a medical and psychiatric history, including records of past and present antipsychotic medications. Results and records of prior antiparkinsonian medication were assessed when possible. All patients were determined to be free of significant cardiovascular, renal, and hepatic disabilities. Each subject was maintained on his neuroleptic medication without change in the dose throughout the period of administration of coded antiparkinsonian medication. All antiparkinsonian medications were stopped at least 3 days prior to baseline measurement.

Procedure

The patients were randomly assigned to two groups, one group (A→T) starting with 100 mg of amantadine twice a day and crossing over to 4 mg of trihexyphenidyl twice a day and the other group (T→A) starting with 4 mg of trihexyphenidyl twice a day and crossing over to 100 mg of amantadine twice a day. Dosages remained constant throughout the study. Group A→T received amantadine as coded medication "b" for 2 weeks; group T→A received trihexyphenidyl as coded medication "a" for 2 weeks. The severity of the parkinsonism and treatment-emergent symptoms were measured at baseline (just prior to beginning the coded medication) and at examinations scheduled for the 1st, 3rd, 7th, 10th, and 14th days on medication. After 14 days placebo was substituted for coded medication. Those patients who experienced significant signs of parkinsonism while receiving placebo were given the alternate to their first coded medication for a second 2-week period, during which they were scheduled for examinations as before. Both periods of coded medication were double blind. The placebo period was single blind. Twenty-one patients were assigned to the T→A group and 20 patients to the A→T group. Two patients withdrew from the T→A group before completing the first medication schedule.

The severity of the parkinsonism was graded on the Simpson-Angus Rating Scale (10) at each examination. The following factors were rated from 0 to 4 in increasing order of severity: gait, arm dropping, shoulder shaking, elbow rigidity, wrist rigidity, leg pendulousness, glabella tap, tremor, and salivation. The sum of the scores of these 9 signs was calculated as a measurement of parkinsonian severity.

The following 8 treatment-emergent symptoms were recorded and scored from 0 to 3 in increasing order of severity at each examination: dry mouth, visual disturbance, urinary hesitancy, hair loss, inability to sit still, confusion, agitation, and tardive dyskinesia.

The average improvement of medication over baseline was calculated separately for the T→A and A→T groups for each examination. The average improvements were compared between the two groups. Student's t test was applied to assess the significance of the values of group differences at each time. At each point Wilcoxon's matched-pairs signed-ranks test was applied separately to each group to determine the significance of improvement following medication over baseline. Side effect scores were totaled and compared for the two groups.

RESULTS

First Period of Coded Medication

Both amantadine and trihexyphenidyl were effective treatments for drug-induced parkinsonism, and their efficacies were determined to be equivalent. The average percent of improvement for amantadine over baseline was as follows: day 1, 10%; day 3, 22%; day 7, 42%; day 10, 52%; and day 14, 53%. The trihexyphenidyl group showed the following improvement over baseline: day 1, 3%; day 3, 27%; day 7, 35%; day 10, 53%; and day 14, 45%. At every dosing time the confidence level for the mean percent of improvement with trihexyphenidyl overlapped the observed mean percent of improvement with amantadine. There was no significant difference between the values derived during the trihexyphenidyl and amantadine administrations. The degree of improvement with the two compounds was well correlated at all examination times. The maximum therapeutic benefit was observed at approximately 10 days. Examination on the first postdrug day showed that neither compound effected improvement of a statistically significant degree at that time. At all subsequent examinations the percent of improvement with amantadine was significant ($p \leq .01$). The percent of improvement with trihexyphenidyl was significant at the 3rd day of examination ($p = .05$) and thereafter ($p \leq .01$).

Table 1 presents a detailed comparison of the efficacy of the medications over baseline and placebo.

Second Period of Coded Medication

This group included 20 patients who experienced recurrence of significant parkinsonism with placebo. These included 9 of the 21 in the T→A group and 11 of the 20 in the A→T group. Data generated from the values at baseline, during placebo, and 14-day examinations on both coded medications were evaluated in two ways. Trihexyphenidyl and amantadine were compared to respective baselines and placebos for assessment and comparison of efficacies. In addition, a direct comparison was made between the efficacies of trihexyphenidyl and amantadine. All 20 subjects evaluated in this group received both compounds in a double-blind, double crossover paradigm. Table 1 compares the improvement in the subjects' clinical conditions brought about by both drugs with values from respective preceding placebo and baseline periods. These values are statistically significant at the .01 and .05 levels as indicated. These data are consistent with the hypothesis that trihexyphenidyl and amantadine efficacies are equivalent. Four pair-wise comparisons can be made among the group means in table 2. In each case, the mean of one sample falls within the con-

fidence level of the other, yielding no statistically significant difference between their means (t test).

Because mean total severity scores in both groups differed between baseline and placebo, we did not calculate the percent of improvement with amantadine over trihexyphenidyl to test their significance and compare the two drugs directly. Instead, we calculated for each patient the difference and percent of improvement of trihexyphenidyl over baseline or placebo, and of amantadine over placebo or baseline. The significance of the deviation of the mean of these differences from 0 was tested. The data in the T→A and the A→T groups and the combined data from both groups were treated separately. Statistically significant results at the .10 level or beyond were not found in any case. These data further indicate that trihexyphenidyl and amantadine are equivalent in efficacy.

Two subjects were withdrawn from the study due to continuing severe parkinsonism. These subjects failed to respond adequately to either compound at the dose level allowed by the study protocol. Although these patients experienced modest relief of symptoms while they received the study medications, their symptoms of parkinsonism were too pronounced to allow continuation on the fixed dose, and they were removed for treatment with more potent doses of standard antiparkinsonian agents. Both subjects were acutely psychiatrically ill and required high doses of neuroleptics (1000 mg per day of chlorpromazine or the equivalent) to control their psychotic symptoms.

DISCUSSION

Amantadine is a putative dopaminergic compound known to be effective in the treatment of idiopathic and postencephalitic Parkinson's disease (9). In a double-blind placebo-controlled crossover study we found that amantadine, at a dose of 100 mg twice a day, was therapeutically equivalent to 4 mg of trihexyphenidyl twice a day in the treatment of neuroleptic-induced parkinsonism in hospitalized psychiatric patients. Amantadine produced fewer and less severe side effects than trihexyphenidyl, although these differences did not reach a level of statistical significance. These data suggest that amantadine is an effective agent in the treatment of neuroleptic-induced parkinsonism.

Neither medication provided complete relief to all subjects, although subjects with remaining symptoms obtained enough relief to allow them to carry out activities of daily living without difficulty. It is possible that a dose schedule that would allow increases in antiparkinsonian medications to accommodate severe symptoms would have provided some subjects with additional symptomatic relief.

TABLE 2
Paired Means of Treatment Group Severity Scores

Treatment Group	Mean Severity Scores				
	Minimum	Lower Confidence Level	Estimated	Upper Confidence Level	Maximum
Baseline	9	12.9	17.1	21.3	32
Trihexyphenidyl	1	5.6	9.18	14.0	25
Placebo	6	12.0	16.6	20.1	34
Trihexyphenidyl	0	5.5	7.7	10.0	16
Placebo	2	11.8	16.7	21.6	29
Amantadine	1	5.2	10.7	16.2	33
Baseline	7	15.0	18.0	21.0	26
Amantadine	3	8.6	11.0	13.4	21

The possibility exists, of course, that other subjects with acute drug-induced parkinsonism who have not been previously treated with antiparkinsonian agents may not respond as consistently as did our test group. Most of the subjects selected for our trial had responded to other antiparkinsonian agents in the past, and this would tend to constitute a biased group. Subsequent clinical trials of amantadine should include a defined sample of patients who have received no prior antiparkinsonian treatment.

In addition, subsequent studies on this model should carefully evaluate the role of rating scales in the data compilation. Our rating scales may not have sufficiently reflected the full range of improvement experienced by the patients. We were unable to quantify some of the data from the Simpson-Angus scales (e.g., handwriting, card-counting) because the active psychoses of some patients imposed an uncontrollable variable upon the instrument. However, we believe that the data generated by physician examination and from rater observation were consistent and reliable.

Since chronic antagonism of striatal acetylcholine may contribute to tardive dyskinesia (4), and since amantadine has no demonstrable atropine-like effects, it appears to be a preferred compound in the treatment of drug-induced parkinsonism. Amantadine could be used in combination with anticholinergics to reverse parkinsonism if satisfactory response was not obtained from currently recommended doses of amantadine. This would in effect decrease the amount of atropine-like compound used and possibly decrease the risk of tardive dyskinesia. Our current evidence indicates that it would be preferable to prescribe a compound that enhances the suppressed striatal dopamine systems rather than suppressing the normally active acetylcholine systems in neuroleptic-induced parkinsonism. However, these speculations must await further clinical trial and epidemiological data from long-term dosing studies with amantadine before any definite recommendations can be made.

A Follow-Up of 78 Patients with Gilles de la Tourette's Syndrome

BY RUTH D. BRUUN, M.D., ARTHUR K. SHAPIRO, M.D., ELAINE SHAPIRO, PH.D., RICHARD SWEET, M.D., HENRIETTE WAYNE, M.D., AND GAIL E. SOLOMON, M.D.

The authors conducted a follow-up study of 78 patients with Gilles de la Tourette's syndrome. Four of the patients were in spontaneous remission; 59 patients taking haloperidol showed an average improvement of 79.5%; and the remaining patients, 3 of whom were taking medication other than haloperidol and 12 of whom were not taking any medication, showed an average improvement of 24.7%. Side effects were the main cause of discontinuing haloperidol. The authors found that response to haloperidol was unrelated to family history of tics, age at onset, type or severity of symptoms, or signs of organicity.

BETWEEN 1965 AND 1973, 80 patients were diagnosed as having Gilles de la Tourette's syndrome at the Payne Whitney Clinic, New York, N.Y. Extensive data have been collected on these patients, all of whom received some treatment with haloperidol. The present study was undertaken to evaluate the clinical course of Tourette's syndrome after chemotherapeutic treatment. We were also interested in the incidence of complete remission, if any, and, because haloperidol has been generally acknowledged to be the drug of choice in the treatment of this syndrome (1–3), whether different types of patients or different symptoms responded differently to haloperidol.

METHOD

Patients selected for the study had been initially evaluated by one of us (R.D.B. or A.K.S.). The diagnostic criteria were onset of symptoms between the ages of 2 and 16; gradual progression from single, simple tics to multiple, often complex movements; development of involuntary vocalizations ranging from grunts to actual words; and varying course with periods of waxing and waning and a shifting of the actual types of symptoms. Coprolalia was considered pathognomonic, but it was not considered necessary for a diagnosis of Tourette's syndrome (4, 5). Patients were assigned severity ratings at the initial evaluation on a 4-point scale according to the following criteria:

1=mild. Symptoms are infrequent and inconspicuous and are often unnoticed. Patients are able to control symptoms substantially in public. Complete absence of symptoms may occur for brief periods.

2=moderate. Symptoms are obvious to all observers but are not necessarily bizarre. Untrained observers might consider these patients merely nervous. Some ability to control symptoms in public exists. No asymptomatic periods occur.

3=marked. Symptoms are obvious and may appear bizarre to some or many observers. Patients may control symptoms somewhat in public, but not for any sustained period of time.

4=severe. Symptoms are obvious, bizarre, and cannot be controlled substantially. Patients attract attention wherever they go.

Of the 80 patients originally evaluated, 2 had died by the time of follow-up (both by suicide). All of the 78 remaining patients completed a questionnaire that asked the following questions:

1. What medications are you taking? What dosages and variations in dosage of these medications have you taken during the past 6 months?
2. What specific symptoms have occurred during the past 6 months? Which have been the most severe? Which have been the most frequent?
3. What is your estimate of the frequency of all of your symptoms on an average day, on a scale ranging from no symptoms at all to 1 symptom every 5 seconds?
4. What specific side effects have you had from medication? Rate each side effect as to severity on a 5-point scale on which 1=slight and 5=extreme.
5. Have you had any periods of complete remission?
6. Have there been times when symptoms were worse? Why?
7. Estimate, in a percentage, how much of an improvement or worsening there has been in symptoms from before treatment to an average day in the last 6 months.
8. Rate the present severity of your illness on a 4-point scale from mild to severe according to the criteria used by the physician at the initial evaluation (de-

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

scribed above). (The patients had no knowledge of the physicians' ratings.)

All 78 patients responded to the questionnaire. Thirty-seven of these patients were evaluated by either or both of the two physicians who had evaluated them initially. The severity of symptoms of all 78 patients was rated without knowledge of the patients' self-ratings. The percent of change in symptoms compared with pretreatment severity was evaluated as follows: complete remission; 90%–100% improvement; 80%–89% improvement; 50%–79% improvement; 10%–49% improvement; and no improvement or worsening.

The 78 patients included 20 women, 57 men, and one transsexual (a male when first evaluated who was a female at the time of follow-up). They ranged in age from 6 to 67. The follow-up evaluation was done 7–103 months after the initial evaluation (an average of 32 months between evaluation and follow-up). Sixteen patients had discontinued taking medication, and 62 were taking medication of some sort: 53 were taking haloperidol, 6 were taking haloperidol plus another medication, and 3 were taking other medications alone.

RESULTS

Interrater reliability was indicated by the proportion of agreement between patient and physician ratings for both methods of evaluating the clinical course ($p=.01$ by sign test) and by a coefficient of correlation for percentage agreement of .83.

Symptoms present at follow-up for all patients included the whole spectrum of symptoms known to characterize Gilles de la Tourette's syndrome. Forty-eight patients (62%) reported various facial tics, most commonly eye blinking and grimacing. Head and neck movements were the next most common, reported by 36 patients (46%). In descending order of incidence were arm and hand movements, 27 patients (35%); leg and foot movements, 23 patients (29%); whole body jerks, 10 patients (13%); and compulsive touching, 7 patients (9%).

Noises, including sniffing, barking, grunting, throat clearing, tongue clicking, and meaningless noises such as "oh," "eeh," and "uh," as well as actual words, were reported by 55 patients (71%). Coprolalia was present in only 13 patients (17%). Echolalia was reported by 3 patients. Other rare symptoms included spitting, biting of the lip, jumping in the air, turning completely around, head hitting, squatting, whistling, obscene gestures, palilalia, and echopraxia.

Thirteen patients were initially rated as mild. Five of these patients were taking haloperidol alone and stated that their symptoms had decreased by an average of 70.8%. The average dose of haloperidol for these 5 patients was 2.7 mg a day. Despite their self-rating of considerable improvement in symptoms, these patients gave themselves an average rating of 1.4 (between mild and moderate) in severity of illness. They reported an average frequency of symptoms of 1 every 15 minutes.

One of the 13 patients who were initially rated as mild reported a 99% improvement in symptoms. This patient was taking 20 mg of haloperidol plus 20 mg of diphenylpyraline hydrochloride a day and felt strongly that both medications were essential to his improvement. Three of the 13 patients reported complete remissions (2 for more than 1 year and 1 for 5 years) and were not taking any medication. Four of the 13 patients had discontinued taking any medication because of side effects and reported an average worsening of symptoms of 12.5%: 3 of these reported no essential change in their condition, and 1 reported a 50% worsening of symptoms.

Twenty-five patients were initially rated as moderate. Sixteen of these patients were taking an average dose of 5 mg of haloperidol a day and reported an average improvement in symptoms of 81.8%. Seven of these patients were also taking small amounts of anticholinergic medication along with the haloperidol. The average self-rating of severity of illness at the time of follow-up of all 16 of the patients taking haloperidol was 1.4 (between mild and moderate). These 16 patients also reported an average frequency of symptoms of 1 every 15 minutes.

Three of the 25 patients initially rated as moderate were taking haloperidol plus other medications; their average self-rating of improvement was 98%. Two of these patients were taking megavitamins plus 4 mg of haloperidol a day (these 2 reported a 95% and 100% improvement in symptoms), and 1 was taking 22.5 mg of haloperidol and 300 mg of thioridazine a day (this patient reported a 99% improvement in symptoms). Two of the 25 patients initially rated as moderate were taking medications other than haloperidol; these patients reported an average improvement in symptoms of 25%. One of these patients was taking 5 mg of fluphenazine a day and reported a 50% improvement, and 1 was taking 75 mg of tetrabenazine a day and reported no improvement. Four of the 25 patients were taking no medication at all: 1 reported a complete remission; 1 had improved 50% spontaneously; and 2 reported no change in their conditions (the average improvement for the 3 latter patients was 16.7%).

Twenty-nine patients were initially rated as marked. Twenty-three of these were taking an average dose of 13 mg of haloperidol a day and reported an average improvement of 80%. Fifteen of these patients also took anticholinergic medications, and 2 of them took 15 mg or 20 mg of methylphenidate a day because of drowsiness caused by haloperidol. The average self-rating for severity of illness of these 23 patients was 1.5 (between mild and moderate). The average frequency of symptoms among these patients was also in the range of 1 symptom every 15 minutes.

Two of the 29 patients initially rated as marked were taking haloperidol plus other medications; these patients reported an average improvement of 65%.

One had been very poorly controlled on haloperidol alone but reported an 80% improvement when taking 300 mg of lithium plus 50 mg of haloperidol a day. The other was taking 150 mg of tetrabenazine and .5 mg of haloperidol a day and reported a 50% improvement. Four of the 29 patients were not taking any medication; their average rating of improvement was 56.3%. Two of these patients reported an 80% improvement, 1 reported a 65% improvement, and 1 was unchanged.

Eleven patients were initially rated as severe. Nine of these were taking an average daily dose of 7.6 mg of haloperidol and showed an average improvement of 71.4%. The average self-rating of these 9 patients at the time of follow-up was 2 (moderate). Six of these 9 patients were taking anticholinergic medications. The average frequency of symptoms reported by the 9 patients taking haloperidol was 1 every 5 minutes.

One of the 11 patients initially rated as severe was taking alpha-methyl-para-tyrosine (AMPT) and reported a 95% improvement. Another of the 11 patients refused medication although he was severely affected by the syndrome; this patient reported no change in symptoms.

In summary, among the 78 patients there were 4 complete spontaneous remissions; 59 patients taking haloperidol alone or combined with other medications who showed an average improvement in symptoms of 79.3%; 3 patients taking other medications; and 12 patients taking no medication. The 15 patients not taking haloperidol showed a 24.7% average improvement. Table 1 presents a comparison of the self-ratings of patients who were taking haloperidol versus those of patients who were not.

Side effects that were bothersome to many patients were the major cause of discontinuing haloperidol. Of the 53 patients taking haloperidol alone or with anticholinergics, akinesia was reported by 51%, drowsiness by 40%, depression by 28%, akathisia by 26%, blurring of vision by 21%, and dyskinesia by 9%. Other side effects were poor concentration, forgetfulness, fatigue, insomnia, dizziness, slurring of speech, and nausea.

Three patients described episodes during which they experienced feelings of depersonalization and paranoia accompanied by slowed mentation. These episodes, which we termed "fog states," a name coined by the first patient to describe them, lasted anywhere from a few seconds to several hours. Although they sounded like a form of psychomotor seizure, we were not able to document this. These episodes were present only during treatment with haloperidol or, in one case, during treatment with phenothiazines or haloperidol. One patient ceased to experience these episodes after treatment with primidone in conjunction with haloperidol and tetrabenazine.

As length of treatment with haloperidol increased, the amount of improvement reported also increased. The 32 patients who took an average dose of 6.3 mg of haloperidol a day for less than 2 years (7–23 months) reported an average improvement in symptoms of 74.3%; the 14 patients who took an average dose of 16.9 mg a day for 2–4 years (24–47 months) reported an average improvement of 80.6%; and the 13 patients who took an average of 8.1 mg a day for more than 4 years (48–103 months) reported an average improvement of 93.4%. The dosage of haloperidol showed no consistent relationship with length of treatment or degree of improvement, although many patients, especially older ones, were able to decrease their dosage with increasing length of treatment (3).

TABLE 1
Ratings of Improvement Made by 59 Patients Taking Haloperidol Alone or with Another Drug and 15 Patients Taking Another Drug or No Drug, by Initial Physician Ratings*

Initial Rating	Haloperidol Alone or with Another Drug		Another Drug or No Drug	
	Number of Patients	Average Rating of Improvement, in Percents	Number of Patients	Average Rating of Improvement, in Percents
Mild (N=10)	6	75.5	4	−12.5
Moderate (N=24)	19	84.3	5	20.0
Marked (N=29)	25	79.3	4	56.3
Severe (N=11)	9	71.4	2	45.7

*The ratings of 4 patients who reported spontaneous remission of symptoms are not reflected in this table.

In addition to the 4 patients who were in remission without medication at the time of follow-up, 1 patient reported a 3-year remission followed by return of symptoms. Five other patients reported brief periods of remission lasting up to 6 months, and 1 patient reported being completely asymptomatic during and for several months after a pregnancy. Many of the patients had asymptomatic periods while taking medication. Sixty-nine of 74 patients who were symptomatic at the time of follow-up (93.2%) told us that periods of emotional stress caused a worsening of symptoms. Eleven patients (14.8%) also mentioned that their symptoms increased when they were relaxing at home. Patients over 30 years old showed less fluctuation in symptoms.

Signs of organic impairment had been evaluated in three ways in 59 of the patients when they were originally seen: abnormalities on EEG, abnormalities on neurological examinations, and signs of organicity on psychological testing (6–8). Thirty of the 59 patients (50.8%) showed positive signs of organicity on more than one of these tests. Twenty-nine patients (49.2%) showed signs of organicity on none or only one of the tests. Twenty-two of the 59 patients were taking haloperidol or other medication. There was no significant difference in response to medication between the group with signs of organicity on two or more tests and those with no signs of organicity or signs on only one test. Nineteen patients were not given all three tests.

We found no correlation between age at onset of ill-

ness or family history of tics and response to treatment.

CONCLUSIONS

In spite of the wide disparity in signs and symptoms among the patients in our study, we have not been able to find any significant clinical difference in natural history or types of symptoms that might be meaningful for prognosis. The slightly better response to treatment of patients initially rated as either moderate or marked is not statistically significant and most likely represents a lack of fine discrimination on the part of both physicians and patients.

It is clear that haloperidol is an effective drug for the treatment of Gilles de la Tourette's syndrome. It still appears to be the most effective medication available (1–3, 9). Its effectiveness, however, is severely hampered by side effects that often force patients to compromise between maximum relief of symptoms and minimum discomfort from side effects or to discontinue the drug completely and live with their symptoms, however disabling they might be. Other medications that we have used during the past several years include many of the antipsychotic phenothiazines, pimozide, tetrabenazine, AMPT, lithium, imipramine, amitriptyline, deanol, methysergide maleate, diazepam, diphenylhydantoin, disulfiram, propranolol, and L-tryptophan. Although some improvement has been seen with tetrabenazine and AMPT (10), it has been sustained in only 1 patient on each of these medications.

Either before coming to us or during the time of follow-up, many of the patients tried such diverse treatments as acupuncture, allergic desensitization, various diets, hypnotherapy, ECT, behavior therapy, and psychoanalysis. Some are still receiving psychotherapy in conjunction with haloperidol. Contrary to the literature, which contains only single case reports (11, 12), we have not seen any substantial improvement through psychotherapy alone in our group of 78 patients.

The Concept of Drug Automatism

BY MICHAEL I. GOOD, M.D.

The drug-automatism hypothesis implies a medication-induced absence of intentionality for self-poisoning and a relative amnesia for serial or single overdosage. Controversy stems from problems encountered in the formulation and verification of the hypothesis. The author reviews the literature, presents a case associated with a proprietary sleeping preparation, and discusses psychopharmacological and psychophysiological elements in the mechanism of drug automatism and its differential diagnosis.

IN 1934 RICHARDS (1) employed the idea of automatism to explain three cases of barbiturate overdosage in which the patients claimed amnesia for taking more than 2 tablets. He noted that 8–10 pills evidently were taken, possibly at intervals, and attributed the phenomenon to barbiturate toxicity. Since then the automatism hypothesis has frequently been used to account for potentially accidental deaths or equivocal suicides due to barbiturate ingestion. However, it is difficult to confirm the hypothesis directly. The existence of drug automatism as a clinical entity is a question of controversy and significance, not only because of the medicolegal and actuarial implications of determining mode of death but also because of the apparent deviation from a strict psychic determinism.

The term "automatism" refers to nonreflexive, directed, and apparently purposive motor behavior performed without full consciousness of what is being done and followed by grossly incomplete recollection or insight. The act may be complex, repetitive, or stereotyped and show lack of judgment or appropriateness. It occurs in such conditions as epilepsy, head trauma, sleep disorder, neurosis, psychosis, personality disorder, intracranial disease, delirium, and intoxication. More than memory is affected even though amnesia may be the only residual sign of prior alteration of consciousness. Automatic behavior may or may not appear meaningful in terms of usual personality, defensive structure, and unconscious impulses, although it is often considered to be an expression of an underlying wish or fear. Alternatively, the behavior can be described operationally in terms of homeostatic tendencies and learned response patterns.

In Richards' original hypothesis, "the knowledge of the need for another tablet persists, while the memory is so affected by the drug that the patient does not realize that he has already satisfied the need, and automatically repeats it at intervals" (1). Ettlinger and Flordh (2) found 27.8% of 500 cases of presumed attempted suicide to be due to "serial consumption" of drugs, a process that can be equivalent to or lead to automatism. Jansson (3, 4) classified 25.4% of 488 varied drug ingestions as automatism cases, which he also defined in terms of serial consumption. The syndrome is widely accepted by physicians and repeatedly described by people who apparently are uninformed about the concept (5–7). On the other hand, some authors have considered the hypothesis a myth based on an erroneous explanation used by patients, relatives, and physicians to rationalize intentional self-poisonings. These patients presumably have unconsciously denied or repressed their true intent to protect against the painful recognition of self-destructive tendencies (6–10). Cases reportedly demonstrating fallacies in the hypothesis, however, have exhibited patent psychopathology, alcoholism, or chronic drug use. Such cases are readily subject to psychodynamic interpretations and do not disconfirm the hypothesis.

The literature lacks clarification of the drug-auto-

Dr. Good is Director of Children's Services, West-Ros-Park Center, 1842 Centre St., West Roxbury, Mass. 02132. He was Resident in Child Psychiatry, Massachusetts Mental Health Center, and Clinical Fellow in Psychiatry, Harvard Medical School, Boston, Mass.

The author wishes to thank Eric Baum, M.D., Herbert Goldings, M.D., Ronald Rubin, M.D., and Richard Shader, M.D., for their helpful comments.

matism hypothesis, specific case reports, and discussion of elements of the syndrome. The following is a case of overdosage of the proprietary sleeping preparation Sominex (each tablet contains 0.25 mg of scopolamine aminoxide hydrobromide, 25 mg of methapyrilene hydrochloride, and 200 mg of salicylamide). It is consistent with the following hypothesis: given predisposing conditions, an initial therapeutic dose of medication taken with or without repetitions can induce a toxic dissociative or delirious state, leading to single or cumulative excessive ingestion that is not a conscious or unconscious attempt at self-poisoning.

CASE REPORT

Police brought a 60-year-old woman to an emergency ward at 7:00 a.m. after she anxiously told her neighbors she had taken "too many Sominex." She was drowsy on arrival and became increasingly somnolent, soon arousable only to deep pain. Blood pressure was stable, pupils were dilated and fixed, and ankle clonus with extensor plantar reflexes was present. Nasogastric lavage yielded only blood-tinged fluid that cleared in a few hours. Lumbar puncture was normal, and a drug screen supported Sominex ingestion. Over the next 24 hours, following a period of disorientation during which she picked at her sheets and spoke incoherently about "bugs in bed," she became fully awake and had a normal neurological examination.

The consulting psychiatrist reported accidental ingestion of about 10 Sominex tablets. For many years the patient had experienced occasional difficulty falling asleep and would read to induce drowsiness. Her sleep difficulty had worsened over the past several months, and she had just purchased a bottle of Sominex. The night before admission she reportedly took two tablets at bedtime and fell asleep, later ingesting more in a soporific state as if "in a dream" that she could barely recall. Some time later she awoke with a high-pitched ringing in her ears and was alarmed when she saw the uncapped, half-empty pill bottle.

She consistently denied suicidal intent, and she had no psychiatric or overdosage history. She used no other drugs, including alcohol, except for occasional, moderate social beer consumption. She had worked as a waitress for years and lately as a cashier. Six and a half years ago her husband had died of a heart attack. Four months prior to admission she had quit work because of dissatisfaction with her duties and salary. A parsimonious woman, she had sufficient bank savings to leave work temporarily and was considering a move to a more modest residence. For a few months she had experienced fatigue, irritability, a 10- to 15-pound involuntary weight loss, and occasional difficulty in concentrating, yet she continued to enjoy reading. She had no anorexia or bowel changes.

In the hospital she was nonsuicidal and unimpaired in memory and cognitive function. The initial diagnosis was overdosage due to drug automatism with mild involutional depression, and she pursued a referral for psychiatric follow-up. Curious about how the ingestion could have happened, she neither transmitted nor reported a sense of depression but could conceive of depression causing her various symptoms. A primarily psychiatric diagnosis for her disorder was questioned, however, when further history revealed that three months previously, as well as several years earlier, she had fainted in the bathroom and struck her head in falling without evidence of prolonged loss of consciousness. She had occasional mild headaches but no discernible signs of significant head injury. EKG, EEG, brain scan, and routine blood studies were normal.

In the absence of positive medical findings and with the question of "masked" depression, she was followed psychiatrically over a six-month period. During this time she gained weight and strength, resumed work, and decided to stop treatment because she felt fine. She formed a therapeutic relationship, presented dreams, and explored losses. Although an impression of atypical depression might be inferred, there was no manifestation of underlying suicidal trends. The possibility of covert alcohol or barbiturate use was never in evidence and seemed unlikely.

DISCUSSION

Cerebral Organic Conditions

Depression notwithstanding, given the patient's history of head trauma followed by fatigue, irritability, insomnia, subjective difficulty concentrating, weight loss without anorexia, and lack of significant depression, it is necessary to consider the diagnosis of posttraumatic syndrome (11). This syndrome may predispose to drug automatism. It can follow even minor head injuries and is characterized by headache, dizziness, insomnia, irritability, fatigue, depression, vasomotor instability, and intolerance to intoxicants. The symptoms can arise in people with a previously normal life adjustment (11).

Jansson (3) noted a clearly higher proportion of cerebral lesions or suspected cerebral organic conditions among the automatism cases in his population. Not less than 49.2% of these 124 cases had such diagnoses as alcoholism, narcomania, epilepsy, and senile dementia, compared with only 24.5% of the control cases. He concluded that these conditions predispose to confusional states with tranquilizers and barbiturates, and he briefly described a case of apparent automatism with serial consumption of meprobamate. In contrast to the incidence of genuine suicidal behavior, the incidence of automatism cases showed no seasonal variation (4).

Goldings (12) described an unpublished case of automatic barbiturate overdosage (nonlethal) in a 49-year-old businesswoman who developed insomnia associated with work concerns. There was no indication of suicidal intent, and she had a history of definite concussion. Stroo's patient (13), who had a history of inebriety, stumbled, hit his head, and could not sleep, after which he progressively ingested 12 mg of scopolamine and developed a psychotic delirium.

Alcohol-, barbiturate-, and other drug-withdrawal states can also predispose to automatism. Withdrawal symptoms leading to use of a new sleeping preparation may potentiate toxic drug effects or may be exacerbated by paradoxical drug effects. Advancing age is another predisposing factor. Psychotropic drug use

in the elderly can have serious side effects either secondary to pathological changes common to this population or due to the natural aging process (14). Aitken and Proudfoot (6) found that patients denying an attempt at self-poisoning despite evidence of overdosage are statistically more likely to be over 40 years old.

Behavioral Toxicity and Sleep

Over-the-counter sleeping preparations can cause acute psychosis with amnesia (15). Surprisingly, considering its components, Sominex has not previously been noted in the psychiatric literature as a drug with the potential to induce automatism. Therapeutic doses of scopolamine ranging from 0.3 to 0.8 mg can produce paradoxical reactions of agitation, hallucinations, and delirium (16). In a psychological study of subjective drug effects, Haertzen (17) observed that scopolamine hydrobromide in doses of 5.0–7.5 μg/kg caused a feeling of impaired memory. Stroo (13) considered that this amnesia for the amount of medication taken could lead to unwitting intoxication; he felt that an amnesia-related sense of futility differentiates such intoxication from a true suicide attempt even though avoidance of depression is sought. Other authors (16) noted the apparent lack of relationship between scopolamine-induced reactions and psychiatric history.

Methapyrilene also has anticholinergic activity (18). Antihistamines can cause central nervous system stimulation or depression, and symptoms of intoxication may be indistinguishable from atropine (or scopolamine) poisoning (16). Usually paradoxical effects arise only with higher doses. Idiosyncratic excitement and delirium also occur with barbiturates (19).

The sedative effect of over-the-counter sleeping preparations is unreliable and tends to disappear with regular use. The decrease in REM sleep is noteworthy. When experimental animals receive centrally acting anticholinergic drugs in sufficient doses, the EEG and behavioral signs of sleep become dissociated—the EEG exhibits a sleep pattern while the behavior indicates wakefulness, often with restlessness and agitation (19). An apparent toxic dissociative state occurs that may differ from other types of delirium and resemble the syndrome of "sleep drunkenness." Bonkalo (20), in reviewing "sleep drunkenness" and violent automatisms of sleep, indicated their association with partial arousal from non-REM sleep. These cases are hypnopompic (not hypnogogic), often associated with sleep deficit and sedative or alcohol use, and followed by recognition of the results of the behavior with appropriate affect, perplexity, absence of denial, and total or partial amnesia.

Delirium and Information Processing

Toxic delirium with automatism may arise from a single standard dosage or from a more complex pattern of serial consumption. Authors since Richards have limited their definition of automatism to serial consumption, which is probably associated with previous barbiturate addiction. Reasons for intentionally repeated or increased dosage include impatience and disregard of time, marked psychic symptoms, tolerance or cross-tolerance with alcohol or other drugs, slow absorption and delayed effects, simple lack of sedative or soporific response, and paradoxical effects (2, 3, 21). Gradual or sudden appearance of excitatory effects at higher concentrations may accelerate or exaggerate the pursuit of relief, with supervening delirium. True automatism may then occur, leading to unintentional single or serial consumption, as if to relieve the very toxic state the drug has induced.

Lipowski (22), in reviewing the perceptual, conceptual, and behavioral impairments in delirium, listed repetition, perseveration, stereotypy, misinterpretation, and overinclusion. The level of consciousness characteristically fluctuates, and EEG changes vary with the mode of altered consciousness. West (23) described the neurophysiological and psychophysiological substrates of dissociative states in terms of information processing. Particularly relevant is the "all or none" nature of information processing by nonconscious, paleocortical structures. In addition, sleep deprivation and a drug-induced alteration of field articulation can cause an undifferentiated, global perception and information processing (24, 25). Impaired field articulation can blur distinctions among dosages, number of tablets, and time intervals, particularly in the absence of another person.

The lack of reports of observed cases of drug automatism may be partly accounted for by the influence of an observer on field articulation, perhaps more so in field-dependent individuals. Even so, many physicians are familiar with examples of inappropriate ingestion of substances by hospitalized patients in a toxic delirium. Finally, the argument that serial consumption of potentially lethal sleeping pills cannot cause death because the patient would first fall asleep (7) fails to consider the fact that metabolic tolerance to hypnotic effects can exist without significantly altering the lethal concentration (19).

Amnesias and Altered States

In considering alternative hypotheses to explain amnesia for overdosage, Dorpat (7) noted that memory loss after regaining consciousness need not have existed at the time of ingestion or while the drug was active. According to this retrograde amnesia hypothesis, the patient is fully aware of overdosage at the time of ingestion but develops a loss of memory due to the drug for events prior to sleep or coma. In contrast, the drug-automatism hypothesis specifies an alteration of consciousness at the time of overdosage but also incorporates the possibility of additional retrograde amnesia. In the absence of an observer at the time of ingestion, it is difficult to distinguish anterograde from retrograde amnesia. Memory of taking an initial dosage is sufficient to suggest, but not to establish, automatism as an alternative to simple retrograde amnesia. Denial, repression, malingering, or retrograde amnesia may account for total absence of recall for any ingestion.

It is important to distinguish denial of the act of overdosage and denial of the motive of suicide. Aitken and Proudfoot (6) made this distinction belatedly in their study of barbiturate automatism: among patients seen for barbiturate poisoning, they selected for further investigation those who either denied the act of self-poisoning or claimed it was due to automatism. Unfortunately, they dropped about half of 69 cases from further consideration because these "miscoded" patients actually had denied the motive of suicide rather than the act of self-poisoning and thus did not meet the initial selection criteria. This elimination of relevant cases probably helped to confirm their conclusion that barbiturate automatism is a myth.

In some instances, the use of amytal or some other hypnotic during an interview may yield a reconstruction of the forgotten event. State-dependent learning and recall have been studied mainly with alcohol. Such studies suggest that 1) recollection depends in part on being in a physiological state like that in which the memory registration occurred and 2) memory impairment depends on the level of intoxication at the time of registration (26).

In an altered state of consciousness, it is possible to manifest intentional or uncontrolled suicidal behavior that is absent outside of that state (7, 27). Ettlinger and Flordh (2) implied this when they described serial consumption making the patient "maudlin" and "dulling his wits" so that "any thought of suicide will be less restrained." Such state-dependent affective behavior should be distinguished from drug automatism in terms of the purpose of the act and the nature and degree of consciousness in the state. However, it is not clear whether state-dependent behavior and toxic dissociative states always differ. The neurophysiological characteristics of various altered states of consciousness await further elaboration. On the basis of available clinical data, it is impossible to rule out the chance that the patient described in this paper ingested an overdose in a state-dependent, otherwise ego-alien attempt at self-poisoning. Nevertheless, insofar as state-dependent behavior is induced by the agent taken, it should be classified along with drug automatism as a behavioral toxic effect of medication.

CONCLUSIONS

Depression and suicidal intent must be considered in apparent cases of drug automatism or accidental self-poisoning. However, consciously or unconsciously motivated suicidal intent need not exist, even though there may be evidence of pharmacological mood alteration or sleep disturbance leading to drug use (a symptom of depression). Attempted suicide (the motive) may be different from self-poisoning (the act). True drug automatism has psychopharmacological and psychophysiological determinants that should be distinguished from psychodynamic features. Increased age, preexisting or suspected cerebral organic conditions, and addiction are commonly associated with drug automatism, which may be preceded by sleep or altered wakefulness. The potential danger of the syndrome is another reason why proprietary sleeping preparations should be subject at least to prescription control, a recommendation made by other authors (16). Physicians prescribing barbiturates should consider automatism as a potentially lethal complication.

Red Blood Cell Catechol *O*-Methyltransferase and Response to Imipramine in Unipolar Depressive Women

BY JONATHAN R.T. DAVIDSON, M.B., B.S., MALCOLM N. MCLEOD, M.D., HELEN L. WHITE, PH.D., AND DAVID RAFT, M.D.

When baseline red blood cell catechol O-methyltransferase (COMT) was measured in 15 unipolar depressive women, the authors found a linear correlation between COMT and response to imipramine (best outcome occurring at low COMT). The results of this study were not related to such variables as intensity of depression, family history, or psychiatric history. The authors suggest that this assay may be useful either as a predictor of response to the drug or as a guide in choosing the optimum dose.

TRICYCLIC ANTIDEPRESSANTS are valuable in the management of depressive illness, but according to various estimates they only help certain patients (1, 2). Even when they help, the depression may not remit fully. In a trial of continuation therapy with tricyclic drugs (3) approximately 40% of the patients required alternative treatment because of an unsatisfactory initial response, even with relatively high doses. Depression is a common disease that can be fatal if improperly treated, yet response to treatment is seemingly capricious. Consequently, several workers have attempted to establish response criteria (4, 5).

Wittenborn and associates (6) demonstrated that tricyclics do not help patients with dependent personalities. In addition, plasma levels of drugs may be as significant as the clinical picture; a pharmacokinetic study (7) has shown marked interindividual variation in levels of nortriptyline at an identical dose. Kragh-Sorensen (8) indicated a relationship between relapse during maintenance therapy and low plasma levels of nortriptyline, but whether or not these levels really correlate with clinical response is a subject of debate (9–12). Glassman and associates (13) emphasized the importance of distinguishing between free (active) and bound (inactive) fractions of the drug in an attempt to clarify this problem. Some researchers claim that pretreatment urinary 3-methoxy-4-hydroxyphenyl glycol can be a useful indicator of response to antidepressants; a high value would suggest a good response to amitriptyline, and a low value would indicate a good response to imipramine (14). Rosenblatt and Chanley (15) found that the ratio of amine to oxidized metabolites varied from 22% to 85% among 6 subjects on a fixed dose of imipramine, which suggests a four-fold variation in the inhibition of amine reuptake following drug therapy. The finding of Prange and associates (16) that thyroid-stimulating hormone can augment the response to imipramine in women implies important roles for both endocrine status and sex of the patient.

The principal mechanism by which tricyclics relieve depression is generally considered to be inhibition of amine reuptake at the synapse (17). If tricyclic antidepressants reduce or eliminate this important route of degradation, amine breakdown by catechol *O*-methyltransferase (COMT) may become more important in the central nervous system (CNS) (18) than it is generally considered. This is consistent with the finding that there is an increase in such methylated products as nor-

metanephrine after tricyclic administration and a decrease in oxidized products mediated via monoamine oxidase (19). COMT is present in the freely accessible red blood cell and in animals it is similar to COMT in other tissues (20). Since this finding is not conclusive for humans, one cannot confidently generalize any findings of red cell COMT activity to its behavior within the CNS. COMT is closely associated with adrenergic receptors (21) and would therefore become relatively more important within the CNS after imipramine therapy, which produces less reuptake of norepinephrine and an increased amount of this amine at the receptor site (22). Cohn and associates (23) demonstrated that COMT activity does not alter in depressed women after they recover and that it is not related to tricyclic drugs, other therapies, nutrition, or menstrual cycle (23).

METHOD

Fifteen unipolar depressive women between the ages of 23 and 69 (mean=42.2 years) were treated with imipramine on a double-blind randomized basis, as part of an evaluation of antidepressants. The starting dose of the 12 inpatients of 25 mg/day of imipramine was increased by 25 mg/day for 5 days to a total daily dose of 150 mg, at which level it remained for an additional 16 days. The 3 outpatients received imipramine for 5 weeks but were only on the full dose (150 mg/day) for the final 3 weeks. The mean length of illness was 20.4 months, with a range from 2 to 84. Using specific criteria (24), we classified 12 patients as neurotic depressive and 3 as psychotic. None of the patients gave a personal or family history suggestive of mania, but 6 subjects had alcoholic or sociopathic relatives, and 1 patient gave a history of suicide in the family. Five patients had had no previous depressions, 4 had one, 2 had two, and 4 had five or more depressive episodes. Informed consent had been obtained prior to treatment in all cases. Clinical ratings were made weekly using Hamilton's and Beck's rating scales, but we will report only pretreatment and terminal scores in this paper. Clinical change is represented by the difference in the raw scores between the two points: a decrease in score indicates improvement, and an increase indicates worsening.

The assay is described in detail elsewhere (25), but we will present a brief description here. Blood specimens were drawn before the initiation of tricyclic therapy in the 12 inpatients, whereas the 3 outpatients had completed a course of imipramine therapy and had been on no psychotropic medication for at least 2 weeks at the time blood was obtained. The inpatients received flurazepam at night as needed. Blood (10 mg) was drawn into plastic syringes containing ethylenediaminetetraacetate, and the red cells were obtained no more than 3 hours afterward. The whole blood was centrifuged, and the red cells were washed in saline, centrifuged again, and lysed. The total amount of COMT was measured (95% is soluble and 5% is membrane bound, according to unpublished observations from our laboratory). A 0.1-ml portion of lysed red blood cell suspension was assayed at pH 7.9, using 0.1 mmol/liter of [^{14}C]methyl-*S*-adenosyl-L-methionine and 2 mmol/liter of 3,4-dihydroxybenzoic acid as substrates, making a total volume of 0.41 ml that also contained 50 mmol/liter of Tris-HCl, 3 mmol/liter of magnesium chloride, and 0.5 mmol/liter of dithiothreitol. COMT activity is described as nanomoles of 4-hydroxy-3-methoxybenzoic acid per hour per milliliter of red blood cells. Cohn and associates (23) have shown that COMT does not alter during the course of depressive illness or after tricyclic drugs have been given; although we did not test this in our sample, 2 female patients who were later treated with imipramine showed no change in this enzyme before and after treatment. We have also shown that COMT activity is not significantly different among normal individuals, primary depressive patients, and secondary depressive patients but is elevated in schizophrenic patients (25).

RESULTS

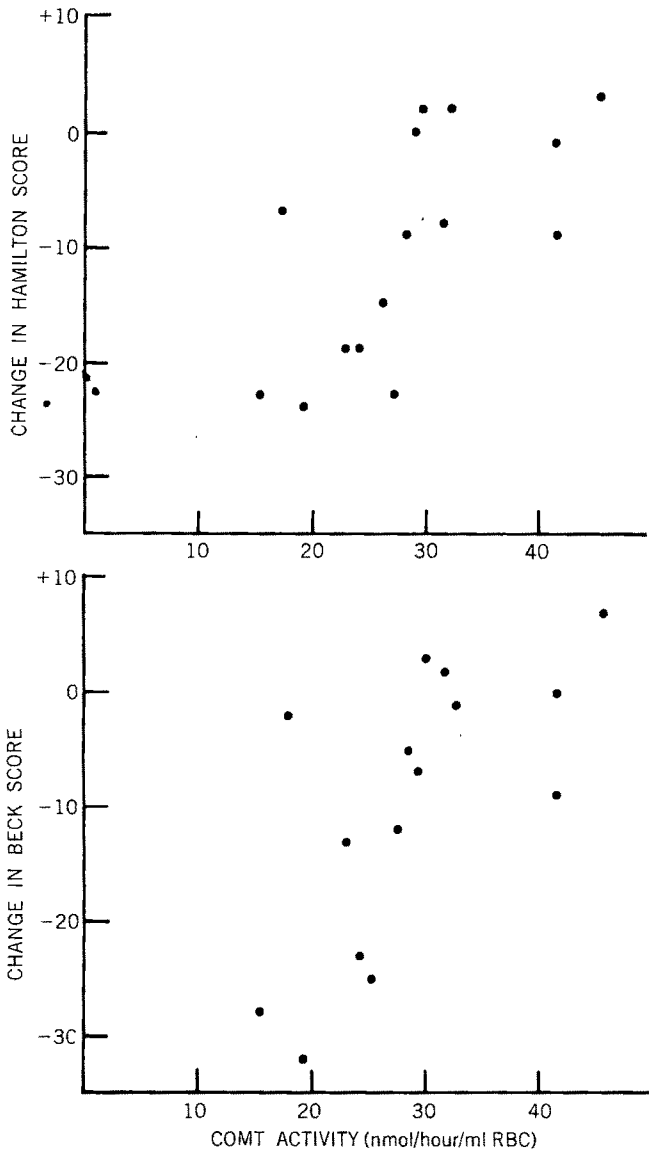

Figure 1 shows that the correlation between baseline COMT activity and clinical change on both depression rating scales is highly significant (Spearman rank-order correlation coefficient=.7, $p<.001$, two-tailed t test). The relationship is linear, i.e., lower COMT corresponds with a better response to imipramine. It should be emphasized that the clinicians were ignorant of COMT activity when rating subjects, and the pharmacologist (H.L.W.) who performed the COMT assays remained unaware of the response to imipramine.

The results indicate that only 3 of 7 patients in the high COMT group (above 29.0 nmol/hour/ml of RBC) improved, whereas all 8 patients in the low COMT group improved considerably. This finding is applicable to both rating scales. There is no difference between these two groups in numbers of previous depressions or in family history. The mean pretreatment scores did not differ significantly (Hamilton Scale=27.1 and 26.0 for high and low COMT groups, respectively; Beck Scale=29.1 and 27.9 for high and low COMT groups, respectively). Therefore, in our sample neither COMT activity nor response to the drug is related to details of family history, previous history, or intensity of the illness.

DISCUSSION

There are several implications that arise from our findings. First, this relatively simple assay could become a predictor of imipramine responsiveness in the dose range we used, at least in women. Second, if COMT is related to the outcome of therapy, it should be taken into account when designing clinical trials of

FIGURE 1
COMT Activity and Change in Score on the Hamilton and Beck scales

imipramine; COMT, along with such other factors as sampling, dose used, duration of treatment, etc., may account for some of the variability in effectiveness. For example, there are reports that imipramine is ineffective in neurotic depression (4, 26), yet we found that if COMT is low, the drug works well for this category of patient. It could be maintained that a maximum dose of 150 mg of imipramine is not enough, given the known variation of plasma levels at a fixed dose (7). Plasma levels are not available to answer the question at this point, but it is possible that higher doses would be required if red cell COMT is high, and when higher doses are employed, imipramine is uniformly effective, regardless of COMT. If that were the case, COMT could still be valuable as a guide to the optimum dose of drug required, thereby shortening the recovery time. Although 150 mg of amitriptyline is considered to be enough in treating outpatients (27), our predominantly inpatient group may require higher doses. We suggest that further work on this matter is needed. An alternative approach would be to develop a nontoxic inhibitor of COMT to be used in conjunction with imipramine in treating "high COMT" depression.

Recent work (28) suggests that it is feasible to consider the clinical picture of depression as being produced either by low amine output or by lowered sensitivity at the receptor. It is interesting to speculate that low COMT might correspond with the latter type and that tricyclic drugs, by blocking reuptake, would render more agonist available at the receptor site with ensuing improvement. On the other hand, a condition of low amine output may respond better to drugs that increase output or reduce breakdown, such as the monoamine oxidase inhibitors (18).

We hope to prepare a later report which should cast more light on the relative roles played by such factors as plasma level of drug, depression subtype, and COMT in the response to imipramine. Another area not yet examined is the role played by the sex of the patient: our results apply to depressed women, and we lack adequate data to express views on the importance of COMT in depressed men.

Therapeutic Effects of Methadone and *l*-α-Acetylmethadol

BY ELAINE KARP-GELERNTER, PH.D., LEON WURMSER, M.D., AND CHARLES SAVAGE, M.D.

Many heroin addicts prefer methadone maintenance treatment to l-α-acetylmethadol (LAAM) because of the "rush-like" effect of methadone. Although there have been no observable differences in the safety and effectiveness of the two drugs, LAAM appears to lead to a more stable, consistent physiological state. The authors report on two patients who had ego defects characterized by severe mood swings. Both patients preferred LAAM to methadone because of its stabilizing effect and smoother action.

Dr. Karp-Gelernter is Project Director, Methadone/*l*-α-Acetylmethadol (LAAM) Maintenance Study, Friends Medical Science Research Center, Inc., 22 Bloomsbury Ave., Baltimore, Md. 21228, and coinvestigator of the Baltimore Veterans Administration research project on chronic heroin abusers. Dr. Wurmser is Associate Professor of Psychiatry and Dr. Savage is Professor of Psychiatry, University of Maryland School of Medicine, Baltimore, Md. Dr. Wurmser is also Clinical Director of Drug Abuse Programs, University of Maryland Hospital, and Dr. Savage is also Chief of Psychiatry and of Drug Dependence Units, Veterans Administration Hospital, Baltimore, Md.

This work was supported by Alcohol, Drug Abuse, and Mental Health Administration grant DA-00415 from the National Institute of Mental Health.

The authors wish to acknowledge the help of Lucy Hahn and the patients and staff at the drug-treatment programs of the Sheppard and Enoch Pratt Hospital, the University of Maryland Hospital, and the Baltimore Veterans Administration.

METHADONE MAINTENANCE, introduced into clinical practice by Dole and Nyswander (1), is the most widely used form of treatment for heroin addiction at this time. Although there is considerable debate about the virtue of a substitute addiction, methadone's positive physiological and psychological effects have been well documented. It is at least as safe as heroin, longer acting, and legal. Dole and Nyswander postulated that methadone provides an answer to the "heroin hunger" induced by a specific metabolic defect. Using clinical evidence, Wurmser (2) found methadone to have not only a substitute action but positive psychotropic effects. Specifically, he noted that in all the patients he has studied in intensive psychotherapy (now 20 cases), "very intense feelings of murderous rage and vengefulness, or of profound shame, embarrassment, and almost paranoid shyness, or of hurt, rejection, and abandonment were discovered. . . . In all of them these feelings of rage, shame, and hurt were reduced as soon as they were on methadone. In a few of them they disappeared altogether; in some they still occurred occasionally but had a less overwhelming quality."

One obvious objection to methadone is that its action is limited to approximately 24 hours, requiring either daily attendance by the patient at a methadone maintenance clinic or the use of take-home medication. The former results in an induced dependence on

the clinic, and the latter affords the possibility of methadone diversion into the black market.

Studies of *l*-α-acetylmethadol (LAAM) are being carried out in the hope of overcoming the objections to methadone. The results of a recently completed comparative study of methadone and LAAM on 99 heroin addicts from whom informed consent had been obtained indicated no observable differences in the safety and effectiveness of the two drugs (3). There was, however, a differential psychological effect. More patients preferred methadone to LAAM because of the familiar "rush-like" effect of methadone that occurs within 2 hours of ingestion. LAAM is followed by no such effect and appears to be a smoother acting medication, leading to a stable, consistent physiological state. Two patients, however, showed a decided preference for LAAM. Upon completing 6 months of participation in the double-blind study (3 months on each drug), both patients (who were able to discriminate between the two drugs because of the "rush") requested LAAM maintenance. We will devote the remainder of this paper to clinical reports of the reactions of these two patients to methadone and LAAM treatments.

CASE REPORTS

Case 1. Mr. A is a 30-year-old heroin addict. He is married and lives with his wife and young child. He completed 2 years of college but has had an erratic employment history. Although trained in computer programming, he never held a job in that capacity. The patient has a psychiatric history of impulsive rage reactions and episodic aggressive behavior along with paranoid symptoms.

His life has been replete with incidents in which he either passively witnessed or actively engaged in violent assaultive activities. His initial experiences with strife started with his family; his parents argued violently. When he was 5 years old, he saw a playmate killed by a truck. Sometime later he witnessed a neighbor commit suicide by jumping out of a window. At 15, he and his friends were taunted with snowballs, and one of his friends stabbed two of the attackers to death. About 4 years later, the patient, having been to some degree provoked by this same friend, shot and killed him. Diagnosed as having a dissociative reaction, he was acquitted from the first-degree murder charge on the grounds of temporary insanity. Shortly thereafter, the patient turned to a homosexual liaison and narcotics. The narcotics had several effects—they muted the shame about his homosexual experience, soothed his despair, and most of all calmed the attacks of terror, guilt, and the welling of murderous rage. Historically, whenever he withdraws from narcotics, his feelings of anxiety and rage become unmanageable.

Our contacts with this patient began after he was arrested for breaking and entering. He was treated at a state hospital, where he was detoxified and released with the recommendation that he receive psychiatric treatment. With a poorly developed ego and a fragile ability to cope, he entered current treatment, which consists of methadone maintenance, drug counseling, and intensive psychotherapy.

Before entering this treatment the patient had used drugs for 10 years and had 10 previous treatments for addiction. He found methadone maintenance only minimally useful and described his acceptance of it with bitter resignation. With methadone he suffered daily fluctuations in mood (ranging from restlessness, extreme irritability, and inability to function) along with a variety of physical symptoms directly related to the number of hours since his last dose of methadone. He stated that he could not function until he received his medication and was constantly attuned to the clock, but he found the rush-like experience that followed his consumption of methadone equally intolerable. He felt that physically and emotionally he remained like a heroin addict and described his daily symptoms as similar to the withdrawal symptoms from heroin addiction. He resented his total dependence on medication and the clinic and repeatedly attempted to free himself from them via detoxification. However, he was unable to remain drug free and found it necessary to return to methadone treatment.

He volunteered to participate in this study in the hope that LAAM would obviate the untoward effects of methadone. When he was treated with LAAM, Mr. A's social, employment, and program status remained stable. He appeared to be better adjusted emotionally and expressed satisfaction with the effects of LAAM. He was transferred after 3 months of LAAM treatment to methadone, at which time his emotional adjustment seemed to deteriorate—he became less cooperative and more unreasonable. His symptoms flared; he expressed impulses to act hostilely, showed paranoid ideation, and was concerned that he would be unable to meet scholastic requirements. He complained about the medication, stating that it was the "same old methadone," and requested that he be placed on LAAM. He reported that while he was on LAAM he did not feel like a drug addict and felt normal for the first time since becoming addicted. He felt better physically and emotionally and was less moody, anxious, tense, and irritable. After a variance in study procedure was obtained, he was returned to LAAM maintenance and again coped effectively.

Case 2. Mr. B is a single man in his mid-20s who lives with his parents in an openly hostile and problematic relationship. Diagnosed in the past as having schizophrenic reaction (chronic undifferentiated type), his symptoms included severe somatic complaints and impulsive behavior. When he entered methadone treatment (1 year before entering the study), psychiatric intervention was recommended and was initiated but not maintained as a continuous part of his treatment. He was, however, treated concurrently with tranquilizers.

His first reactions when placed on LAAM were malaise, headaches, and anxiety about the medication. Nevertheless, he did not request termination from the study, and these symptoms abated spontaneously. During this time his counselors, nurses, and staff noted diminished severity of symptoms and charted overall improvement. When he was transferred back to methadone, his somatic symptoms flared. He exhibited bizarre behavior, threatened the life of his counselor, and set fire to his desk. The combination of tranquilizers, methadone, and psychiatric intervention calmed him somewhat.

After completing this study, Mr. B requested LAAM maintenance. His reasons were similar to those of Mr. A—on LAAM he felt more comfortable, better adjusted, less like an addict, and less irritable. He too suffered less from intolerable fluctuations in mood and body state. The addition of tranquilizers to methadone treatment did not alleviate these daily shifts in physical and psychological symptoms. LAAM appeared to have the ability to regulate the patient's well-

being better than the combination of tranquilizers and methadone. When he returned to LAAM maintenance, the patient's functioning improved and he voluntarily gave up the use of tranquilizers.

Both patients can be characterized as having moderate to severe ego disturbances and extreme problems with impulse control. To them, methadone, although preferable to abstinence, had severe limitations. Although it controlled heroin craving, it did not alleviate emotional or physical symptoms. LAAM proved to be a more effective chemotherapy for both patients—they felt more normal and stable under this regime than under methadone maintenance.

SUMMARY

Methadone maintenance may be an effective adjunct for patients with ego defects characterized by severe mood swings and inability to control feelings of rage and aggressive impulses. Although it is premature to generalize about the specific psychotropic action of LAAM, the clinical data on two patients suggests that, because of its stabilizing effect and smoother action, LAAM may provide an even more viable form of treatment for such heroin addicts. At the same time, its lack of a "high" may make it less attractive for the patient to whom euphoria is more important than impulse control.

Adolescent Parricide: A Comparison with Other Adolescent Murder

BY BILLIE F. CORDER, ED.D., BRENDA C. BALL, PH.D., THOMAS M. HAIZLIP, M.D., ROBERT ROLLINS, M.D., AND RALPH BEAUMONT

The authors examined the available data for 10 adolescents who had been charged with parricide and compared these with data for matched groups of 10 adolescents charged with murdering another relative or a close acquaintance and 10 charged with murdering a stranger. They found significant differences between parricidal adolescents and other homicidal adolescents on personality, family, social, and follow-up adjustment variables.

MANY OF THE STUDIES of environmental and psychological characteristics of adolescents who have committed parricide have been based on the case studies of 1 or 2 adolescents (1–3). There have been no controlled comparisons of parricidal adolescents with matched groups of adolescents who committed other types of homicide. Follow-up of parricidal adolescents has also been rare. Only one study reported post-treatment follow-up of homicidal adolescents (4); the authors found that 1 boy who attempted to kill his parents was returned to his home.

Lander and Schulman (5) hypothesized that acting out of intense hostility engendered by destructive parent-child relationships occurs along a continuum. They saw parricide as a culmination of intense neurotic conflict and other murders as characterized by simple, primitive acting out by impulse-ridden personalities; therefore, parricide and other murder are committed by persons at different points along a spectrum of ego structure and development.

Objective comparisons of factors present in different types of homicide committed by adolescents have not been reported. Many observations and generalizations on parricide have been based on groups of case histories that included adolescents who only threatened homicide as well as those who attempted homicide unsuccessfully (4), even though Sendi and

Dr. Corder and Dr. Ball are Codirectors, Psychological Services, Child Residency Training Program, Dorothea Dix Hospital, Raleigh, N.C. 27611, where Dr. Haizlip is Director of Child Psychiatry Training, Dr. Rollins is Director of Regional Forensic Psychiatry Services, and Mr. Beaumont is Research Assistant.

Blomgren (6) indicated that adolescents who threatened or attempted homicide might have been significantly different in many personality and environmental history characteristics from those who actually committed homicide.

Behavioral observations of adolescents who committed parricide have been combined with observations of those who murdered other relatives or close acquaintances in most studies of murder by adolescents (7, 8). This further complicates any clear picture of adolescent parricide. Little definitive information is available from research studies to establish whether adolescents who commit parricide are significantly different in personality characteristics, environmental factors, and posttreatment adjustment from adolescents who murder other relatives or total strangers.

In this paper we aim to present and compare data on 30 adolescents charged with murder: 10 were charged with parricide, 10 were charged with the murder of a relative other than their mother or father or of a close acquaintance, and 10 were charged with the murder of a person whom they had not known. We applied selected personality, family, and environmental variables as well as follow-up variables on behavioral adjustment in comparing these three groups.

The following questions were explored: 1) Do these group comparisons support the idea of a spectrum of differences in ego structure and development of impulse control among adolescents who commit different types of murder, as suggested by Lander and Schulman (5)? 2) Did the three groups have significantly different patterns of parental interaction and intimacy? Specifically, did the parricidal group show significantly different patterns of strong attachment to one parent, as hypothesized by Sadoff (2)? 3) Were different levels and patterns of disorganization and conflict present in the home environments of the three groups? Did they show histories of parental brutality and modeling of aggressive behavior, as reported for adult murderers by Satten and associates (9)? 4) Do significant differences in social and sexual outlets among the three groups support the idea of a lack of alternative means of tension discharge outside the family, suggested by Scherl and Mack (1) as a precipitating factor in parricide? 5) Do significant differences in follow-up data on the posttreatment adjustment of the three groups support the contention of Duncan and Duncan (4) that adolescents who commit or attempt parricide may adjust satisfactorily with no further lapses of impulse control but that other groups of adolescents who commit murder may repeat the offense?

PATIENTS

We reviewed the records of a regional forensic psychiatry hospital unit to select all adolescents admitted for observation during a 14-year period who were charged with murder by the region's juvenile court system. During the 14-year period 12 adolescents who were evaluated in this unit had been charged with parricide, out of a total group of 76 adolescents between the ages of 13 and 18 who were hospitalized for evaluation and observation on a charge of murder. The records of 2 of the adolescents charged with parricide were not available. The remaining 10 adolescents (9 boys and 1 girl) had been charged with 2 matricides, 6 patricides, and 2 matricide-patricides. Their records were matched as closely as possible for age, sex, IQ, socioeconomic level, and date of admission with those of adolescents in two control groups.

One control group consisted of 10 adolescents who had been charged with murdering a relative other than their parents or a person with whom they had a long-standing relationship. The other consisted of 10 adolescents who had been charged with murdering a person with whom they had no relationship before the murder. Psychiatric diagnoses were not available for most of the 30 adolescents; the hospital records listed the majority of them simply as "without psychosis." The average age of the 30 adolescents was 16 years, 6 months; the average number of years for which follow-up data were available was 4½.

METHOD

Follow-up data for each patient were obtained by reviewing hospital, prison, and outpatient clinic records, test reports, and social history data in addition to interviews with hospital and clinic staff and prison and parole officials. Using data from these sources, 31 social history, personality, and follow-up adjustment characteristics were determined by three researchers (B.F.C., B.C.B., and R.B.) to have been present or absent according to available data. We used presence-absence checklists to record these data. Additional data were obtained in some instances until 100% interrater agreement could be reached on all items.

The 19 variables dealing with personality, family, and environmental characteristics are listed in table 1.

Six variables were determined from the follow-up data available for the patients' behavior and adjustment after the murder. Five of these variables are listed in table 1; the sixth was a general adjustment level rating made by the agency or institution responsible for the patient.

Postrelease behavior data were gathered for paroled or released adolescents only. The 6 following variables were examined: 1) heterosexual contacts (typically dating or marriage), 2) adequate school or job adjustment (based on rating by parole officer), 3) social outlets (clubs, friends outside the family, hobbies), 4) re-arrest record or police charges, 5) incidents of self-destructive or aggressive behavior, and 6) acceptance by family (whether the patient returned to live with family or maintained close contact).

The number of patients who demonstrated each of the 31 research factors was counted for each of the three groups. Total scores for each factor of each

group were compared by means of Fisher's exact test applied to the resulting contingency table for each factor.

RESULTS

The results of our analysis are shown in table 1. Adolescents who were charged with parricide showed the following significant differences from one or both of the two control groups: fewer typical adolescent sexual outlets and social relationships (manifested by differences in dating patterns); fewer indications of poor impulse control or aggressive behavior; more indications of chronic physical abuse by parents; more indications of overattachment to their mothers; more evidence of atypical sexual stimulation by parents; greater frequency of chronic abuse of a passive mother by the father; family patterns of absent fathers; and more instances of amnesia for the murder act.

The adolescents who were charged with murdering strangers were significantly more likely than the parricidal group to have a history of poor impulse control, aggressive behavior, and previous arrests and sentences to training schools. This group was significantly more likely than the group of adolescents charged with murdering a relative to have been identified by some agency as needing psychiatric treatment before the crime, to have shown instances of drug or alcohol abuse, and to have shown some evidence of planning the crime.

All three groups of homicidal adolescents showed a similarly low incidence of self-destructive behavior and almost no drug or alcohol intoxication at the time of the crime. A high level of family and home disorganization was present in all three groups, along with evidence of marked maladjustment and behavior disorders in the parents, although the types of parental disorders differed.

Follow-up information for the 30 adolescents covered at least 2 years and averaged 4½ years. These data show that the parricidal group had adjusted well outside prison with minimum psychiatric treatment and intervention. Only 1 patient in the parricidal group was incarcerated at the time of follow-up, and only 1 of the 20 other patients was on parole. Four of the patients in the parricidal group returned to their families, and all 8 of the patients in the parricidal group for whom follow-up data were available had been accepted by their families, maintaining frequent contact and, in some instances, living with the remaining parent.

As a group, the 20 adolescents in the control groups adjusted fairly well to the structured prison environment, often making "honor grade" status and partici-

pating voluntarily in work-study programs. Instances of aggressive behavior among these adolescents, however, were more common, even within the prison setting, than among the adolescents in the released parricidal group.

DISCUSSION

As a group, the 30 homicidal adolescents studied were born into homes that typically showed a high degree of family disorganization characterized by intense marital conflict, economic insecurity, parental brutality, and lack of social or community ties. One or both parents of 19 of the 30 adolescents showed evidence of extreme maladjustment, e.g., chronic alcoholism, repeated hospitalizations for psychosis, many incarcerations for criminal acts. These findings support some of the hypotheses (based on small numbers of cases) of authors such as Duncan and Duncan (4) and Lander and Schulman (5), who described destructive parent-child relationships and lack of nurturance and hypothesized that these may lead to acting out of intense hostility and homicidal behavior. The differences among the three groups of adolescents we studied may help to predict what type of adolescents murder their own parents rather than acting out their hostility against others.

Although each of our groups showed roughly equal numbers of parents with some evidence of extreme maladjustment, they showed different and characteristic patterns of parental difficulties. The fathers of 6 of the 10 adolescents charged with parricide were alcoholic. The fathers or mothers of 5 of the adolescents charged with murdering a relative had been diagnosed at one time as psychotic. A parent and/or other immediate family member of 8 of the adolescents charged with murdering a stranger had served a number of prison sentences for non-family-linked crimes, but in the other two groups overt hostility was more typically acted out by the parent against the immediate family, intensifying intrafamily conflict.

It seems to us that adolescents charged with murdering strangers came from homes in which antisocial behavior was a parental pattern that resulted in the incomplete socialization of the children, who, like the adolescents described by King (10), tended to view the victim as an object or obstacle interfering with some immediate need for gratification (6 of our 10 adolescents charged with murdering a stranger killed during robbery and 2 during rape). This group of patients began to act out primitive aggressive impulses early in life, and all 10 had a long history of impulse control problems characterized by aggressive, destructive behavior. Nine of the 10 had been placed in training schools or other institutions, which substantiates a long history of recidivist behavior. This also removed the adolescents from their parents as possible victims for long periods of time.

The adolescents who were charged with murdering a close acquaintance or a relative other than mother or father appeared to show less marked but similar histories of difficulty with impulse control, aggressive behavior, and incarceration. However, the motives and circumstances surrounding these murders tended to show some indications of deeper, continued interpersonal conflict and symbolic meaning rather than the simple, primitive acting out observed in the adolescents charged with murdering strangers. One adolescent in the group charged with murdering a relative murdered a woman who often acted as a mother surrogate. He killed her during a physical fight over money, but he referred later to his being angry about her expressions of favoritism toward her own children.

The 10 adolescents who were charged with parricide probably had fewer alternative modes of reaction to stress than the adolescents in the two control groups, as indicated by fewer social outlets, fewer sexual outlets, and fewer instances of aggressive behavior or lapses of impulse control. The mother-father-child relationships for the parricidal group showed two typical pattern differences from the control groups.

All 6 patients charged with murdering their fathers came from homes in which the father was a chronic alcoholic who was severely abusive to both the patient and his or her mother. The mother appeared to passively endure this abuse and maintained a close, positive, nurturing relationship with the patient. In the control groups, however, no close relationship with either parent seemed evident. The mother's relationship with the parricidal adolescent seemed to show little evidence of the intensely seductive or sexual mother-child interaction suggested by many studies.

The 2 patients charged with murdering their mothers showed patterns described by many previous studies (1–3), i.e., overly close, sexually provocative, seductive relationships with the mother and a distant father whose work required extended absences from the home. The father of 1 of the patients charged with murdering both parents was abusive to the mother, whose behavior was described by the patient as seductive toward him.

Sargent (11) hypothesized that the murderer who is a child may often be acting out covert commands and wishes from one parent or from others in the environment. Although it is not possible to prove that this kind of lethal situation exists in the home environment, it is interesting to note that the majority of the remaining parents of our parricidal adolescents remarried soon after the murder. In addition, follow-up of 8 of the adolescents charged with parricide indicated that 7 were maintaining close contact with their families (sometimes after very brief periods of hospitalization) and that 4 of these were living in the home of the remaining parent.

Subtle Neuropsychiatric Sequelae of Carbon Monoxide Intoxication: Two Case Reports

BY JAMES W. JEFFERSON, M.D.

Carbon monoxide intoxication may result in subtle neuropsychiatric abnormalities that can be overlooked, misdiagnosed, or not fully appreciated. The author describes two patients who developed subtle but troublesome emotional and cognitive problems following carbon monoxide poisoning and stresses the value of sequential neuropsychological testing and judicious psychiatric counseling in such cases.

In 1940 Raskin and Mullaney (1) reviewed the literature on the effects of carbon monoxide (CO) asphyxia and noted a wide variety of neuropsychiatric abnormalities, including Korsakoff's syndrome, cortical blindness, a syndrome resembling multiple sclerosis, peripheral neuritis, dementia, psychosis, parkinsonian symptoms, Wernicke's aphasia, and manic-depressive psychosis. This point was further emphasized by Garland and Pearce (2), who observed that almost every known neurological syndrome had been reported as a complication of CO poisoning. Smith and Brandon (3) noted that such neuropsychiatric sequelae were not always dramatic and pointed out that "the temporal relationship of the sequelae to the CO poisoning was often appreciated by the patients and their informants but not by their physicians." They stressed that in order to design appropriate treatment the physician must be aware that a somatic disorder is responsible for these patients' altered psychosocial behavior.

The following two cases are reported as examples of the subtle neuropsychiatric impairment that can follow CO poisoning. They illustrate the value of psychiatric evaluation and sequential neuropsychological testing in defining the nature of the disability and in mapping a therapeutic course. They also show the importance of avoiding inappropriate therapeutic interventions that might be used if the therapist failed to consider the organic substrate of the illness.

Dr. Jefferson is Assistant Professor, Department of Psychiatry, University of Wisconsin Center for the Health Sciences, 1300 University Ave., Madison, Wis. 53706.

CASE REPORTS

Both patients were exposed accidently to high CO concentrations and were brought to University Hospital's emergency room early one morning in June 1973.

Case 1. Ms. A, a 23-year-old graduate student, awoke from sleep early that morning with a severe headache and shortly afterwards lost consciousness. When she reached the hospital she was awake, but was irritable, nauseated, complained of headache, and on one occasion vomited. Her face was flushed and she was lethargic and unable to answer questions appropriately. Arterial blood initially showed a CO saturation of 52%. Treatment with 100% oxygen, which was begun in the ambulance, was continued. In addition she received both methylprednisolone and mannitol to combat cerebral edema. Later that morning arterial blood CO saturation fell to 14% and by that afternoon returned to normal. A neurological evaluation was within normal limits and Ms. A was discharged two days later.

The following day, however, she was readmitted because

of generalized malaise, anxiety, and blurred vision. At that time it was felt that she was having a delayed psychological reaction to the fact that she almost died or had major central nervous system damage. By the next day she had improved enough to be discharged, although she showed some difficulty with recent memory. During follow-up Ms. A complained of apathy, fatigue, irritability, and unprovoked crying episodes. These symptoms prevented her from taking her scheduled doctoral examination that summer and, because of continued distress, she was referred for psychiatric evaluation and neuropsychological testing.

Case 2. Mr. B, a 35-year-old postdoctoral lecturer, was mildly confused on admission and unable to recall the events leading to his hospitalization. He complained of a moderate frontal headache. Physical examination was normal with the exception of red, mottled skin and left upper-extremity weakness. Arterial blood CO saturation was initially 51%. Treatment with 100% oxygen was given. By midmorning the CO saturation was 10% and later that day fell to 4%. In addition intravenous methylprednisolone was administered to reduce cerebral edema. Oxygen therapy was continued for an additional 24 hours, and Mr. B was discharged the next day. Beside the severe CO intoxication it was felt that while unconscious the patient had developed pressure-induced monoparesis of the left upper extremity.

Following discharge Mr. B complained of apathy, fatigue, irritability, and disturbed interpersonal relationships. Whereas he had been an accomplished and enthusiastic sailor, he now complained of relative indifference about the sport and noted an impaired ability to make the fine tactical decisions that had previously earned him considerable racing success. His difficulty with problem solving and lower resistance to the stresses of work hampered him professionally. Because of his continuing distress he was also referred for psychiatric evaluation and neuropsychological testing.

FOLLOW-UP

Neuropsychological Test Results (July 1973)

Ms. A's neuropsychological test results were generally considered to be within normal limits. She gave repetitive test evidence of very superior abilities in psychometrics, in abstraction-concept formation, and in a variety of other problem-solving measures sensitive to cerebral impairment. The results showed no evidence of motor deficits or sensory discrimination errors.

Ms. A did not perform quite as well on several measures of memory span and concentration as she did on other portions of the battery. This was thought significant only because of her very superior performance level on the overwhelming majority of tests presented her. In view of the overall excellence of her neuropsychological abilities and her Minnesota Multiphasic Personality Inventory (MMPI) profile, these marginally inadequate scores were felt to reflect interference effects from anxiety rather than a central nervous system deficit or dysfunction.

The MMPI profile was suggestive of moderate depression and anxiety. It was not possible to determine whether this was due to long-standing neurotic problems or was a situational reaction to her recent life-threatening experience. It was suggested that the referring physician and Ms. A further explore her attitudes and needs and that she be given massive (and entirely legitimate) reassurance that her cognitive functions were unimpaired and were clearly compatible with her educational program and goal.

Mr. B showed no impairment vis-à-vis test norms from nonneurological control subjects on any of the abstraction, memory, psychomotor-problem-solving, verbal-language, and other cognitive tests administered, and his motor proficiency and sensory discrimination abilities were within normal limits. It is possible that prior to the CO poisoning he might have displayed an even more superior performance on some of these tests, but there was no way to confirm this.

Mr. B showed evidence of being a mediocre speller and performed only within average range on the Wechsler Adult Intelligence Scale (WAIS) digit span recall test. However, it was difficult to interpret these isolated performance decrements as residuals of the CO poisoning because his performance on many tests considered sensitive to significant cerebral dysfunction was unimpaired.

His MMPI profile suggested considerable emotional and affective disturbance, characterized by depression, heightened awareness of and preoccupation with physical symptoms and body integrity, and a very high anxiety level. The MMPI profile showed that he was more than ordinarily introspective, worried, and, perhaps, obsessive regarding subjective "mental changes" associated with the CO poisoning. It was suggested that attention be focused on emphasizing his generally excellent test performance and encouraging his awareness that his residual symptoms (numbness of the left arm, difficulty in concentration, and disturbed short-term memory) were gradually improving.

Psychotherapy

Explorative and supportive psychotherapy was pursued with Ms. A and Mr. B, both individually and as a pair, over several months, with interview frequency decreasing in relation to clinical improvement. As therapy progressed it became increasingly apparent that the personality changes were clearly related to the poisoning. Consequently therapy was mainly supportive, reinforcing appropriate coping mechanisms while the patients gradually regained their premorbid level of functioning. During the following year periodic contacts with them confirmed that both had returned to their former high level of professional performance and had regained their zest for life.

A year after the poisoning neuropsychological testing was repeated to confirm the clinical impression of improvement, to probe for subtle persistent abnormalities, and to compare reevaluation results with the initial test results.

Neuropsychological Test Results (1974)

After one year Ms. A 1) had improved on the sustained auditory attention test, performing within the

unimpaired range (in 1973 she had received a mildly impaired score); 2) showed no improvement on the digit span subtest of the WAIS, with her performance continuing to fall within the average instead of the above-average or superior range, which might indicate a very mild relative impairment in immediate verbal memory span; 3) demonstrated a slightly slower finger-tapping rate than was noted in the previous examination; and 4) showed dynamometer grip strength and kinetic tremor test scores identical to or better than her initial scores and well within normal limits.

The MMPI profile showed improvement in Ms. A's emotional status, with less evidence of depression and anxiety. In those areas in which poorer performances were found on the 1974 than the 1973 test, the differences did not exceed the usual test-retest reliability of the measuring instruments.

After one year Mr. B 1) consistently showed significantly improved performances on all tests on which he initially received less than superior scores (including several measures of arithmetic computational ability and digit span recall); 2) continued to score somewhat below educational expectancy on the spelling subtest of the Wide Range Achievement measure (in the initial testing his grade score equivalent was 9.9 and in 1974 it was 10.2); and 3) had unimpaired performance on tests of sustained attention and concentration and rapid number-letter sequencing ability. A personality screening inventory showed changes compatible with his improved affective-emotional functioning.

In both cases periodic reevaluation was recommended because of the possibility of delayed adverse cerebral/cognitive reactions.

DISCUSSION

There have been numerous reports of the neuropathological changes following carbon monoxide intoxication, the most recent by Ginsberg and associates (4. 5). Since cerebral gray matter is more sensitive to hypoxia than white matter, the fact that leukoencephalopathic lesions are predominant suggests that factors other than hypoxia are critical. These may include metabolic acidosis, hypotension, cerebral edema, and peculiarities of blood vessel distribution in particular areas of the brain. Historically, lesions of the globus pallidus have been considered characteristic of CO poisoning, although such changes lack diagnostic specificity. Much of the neuropathological variation reported from study to study may be due to differences in severity of exposure rather than to more fundamental pathogenic differences. Certainly all central nervous system tissue must be considered vulnerable and even peripheral nerve abnormalities have been reported.

In the face of such an anatomical substrate it is not surprising that clinical abnormalities can be widely variable. Gross neuropsychological sequelae have been well recognized and thoroughly discussed (1, 3, 6, 7). Of particular importance is the observation that a "pseudorecovery" may occur, only to be followed days later by an acute relapse that may be severe enough to result in permanent disability or death (2, 7, 8). The etiology of this phenomenon is unclear.

More attention to long-term follow-up is needed to elucidate and define subtle neuropsychological abnormalities. In a preliminary report evaluating 147 survivors of CO poisoning, Smith and Brandon (6) noted that 50% of the victims had an abnormal mental status on regaining consciousness (irritable and restless, 21%; depression, 18%; anxiety, 4.3%; prolonged delirium, 20.3%). A three-year follow-up of 63 of these patients revealed that 33% had personality deterioration and 43% had persistent memory impairment. Smith and Brandon also noted a high correlation between personality deterioration and memory impairment and found that the level of consciousness at the time of hospital admission correlated significantly with development of these problems. They described a syndrome of "affective incontinence" that occurred in 8 of the 63 patients, a personality change that took the form of irritability, aggression, and violence in association with impaired cognition.

Veil and associates (7) evaluated sequelae of CO poisoning in 108 victims one year after intoxication. Their tests were designed to examine psychological, socioprofessional, psychopathological, and physiopathological factors. The patients were compared with a control group of patients who had experienced a loss of consciousness not caused by CO poisoning. They concluded that all of the CO victims had some symptoms that could be identified as sequelae to the poisoning. Since abnormalities were diverse in both nature and severity, the existence of a common syndrome could not be confirmed. They felt that the consequences of such a disability might vary considerably, depending on the person's basic personality and his or her social and professional role. Among abnormalities noted were difficulties with structural-spatial relationships, shortened attention span, sleep disturbances, fatigue, memory (especially recent) deficits, and a global impairment of physical aptitude. These abnormalities were frequently of such a subtle nature that they were detectable only by extensive and sensitive evaluation techniques.

CONCLUSIONS

The studies described above illustrate that an appreciation of the protean neuropsychiatric manifestations of CO poisoning is essential if appropriate therapy is to continue beyond the acute phase of intoxication. Subtle alterations in affective and cognitive functioning are frequent occurrences and are causally related to the effects of carbon monoxide on cerebral functioning.

Although both patients described what they considered to be unequivocal personality changes following the poisoning, there was an initial tendency for their treating physicians (internists, psychiatrist, and testing psychologist) to ascribe these symptoms to psychoneurotic causes. An in-depth review of pertinent literature and a series of psychiatric interviews allowed a clear delineation of the temporal relationship between the poisoning and the personality changes. Subsequent therapy was appropriately tailored to the situation and their symptoms gradually abated. Neuropsychological testing a year later confirmed this observation.

The value of sequential testing is clear, since the initial test battery represented only one point in time and could not define the contribution of the morbid event to the abnormalities noted. In addition, because both patients had superior intellectual capabilities, considerable impairment occurred without the test results falling below the limits of normality. Only when there was clear improvement on the repeat testing did the degree of initial impairment become evident.

The Psychiatrist in Primary Medical Care Training: A Solution to the Mind-Body Dichotomy?

BY ALAN M. LAZERSON, M.D.

The author calls attention to developing changes in medical training that may provide an appropriate setting for overcoming the dichotomous view of mind and body, of psychological medicine and "scientific medicine." Primary care training programs that include liaison psychiatry may be the vehicle for solving this persistent problem.

IN 1940, Deutsch and associates (1) wrote:

> The intimate relationship between psychological factors and bodily function has always been recognized in medicine, but the task of conveying the importance of this relationship to . . . students has depended more on the individual teacher's interest than on any considered program. To facilitate a study of the problem and to formulate a teaching program, a collaboration between psychiatrists and internists was considered essential. This hospital, because of its compactness, excellent clinical material, and general administrative and clinical organization, offered an unusual opportunity for this type of endeavor. The teaching was adapted primarily to a somewhat changing group of fourth year medical students, the resident staff, and many of the junior visiting physicians. (p. 1)

Almost 25 years later Reichard (2), at the same hospital, wrote,

> The medical chart of today offers convincing evidence that the tradition of medicine is strongly antagonistic to treating psychological data in the systematic, scientific manner that is accorded to physiological data. The ideal of contemporary medicine should be to eliminate this illogical distinction. The rational, critical method used by medical doctors to deal with physiological data should be extended to include psychological data. At the present moment, unfortunately, this goal is completely out of sight.

Dr. Lazerson is Senior Psychiatrist, Boston City Hospital Primary Care Training Program, and Associate Professor, Division of Psychiatry, Boston University School of Medicine, 80 East Concord St., Boston, Mass. 02118.

This work was supported in part by contract 1-PE-34074 from the Department of Health, Education, and Welfare and grant 842 from the Robert Wood Johnson Foundation.

> Medical doctors lack a conceptual system that would enable them to observe and appreciate psychological events. In most cases they lack the skill to set up a therapeutic alliance which would permit them to obtain information from their patients and then to use that information to influence their patients in a psychologically effective manner. And last, the tradition of medicine operates to preserve an arbitrary and obstructive distinction between psychological and physiological events. (p. 202)

Unfortunately, this experience at an outstanding teaching hospital with a history of excellent leadership and faculty in both psychiatry and medicine is typical, as are the aspirations and the disappointment expressed in the two quotes. The importance of studying and understanding the doctor-patient relationship and the psychological reactions to organic illness, the fallacy of psychiatric diagnosis by exclusion, and the problems in history taking and patient management (1) are all well known now by psychiatrists who teach medical students, house officers, or practicing physicians. Yet, in spite of long-term and widespread teaching of psychological medicine at all these levels, little progress seems to have been made in these areas in the population of practitioners at large (3, 4). Although certain psychological factors that interfere with such learning have long been appreciated, the extrinsic factors, "the tradition" referred to by Reichard, have proven to be an impasse.

ATTEMPTS TO OVERCOME THE MIND-BODY DICHOTOMY

The purpose of this paper is to call attention to developing changes in undergraduate and graduate medical training that may, at last, provide an appropriate setting for overcoming the dichotomous view of mind and body, of "functional" and "organic" illnesses. Psychiatrists who teach medical students, house staff, and other physicians would do well to be alert to these changes.

In 1966 a major public review of our medical care system, the Report of the Citizens Commission on Graduate Medical Education (referred to as the Millis Commission Report) (5), brought the term "primary physician" to public attention and identified the growing shortage of primary care physicians as the leading problem confronting our medical care system. The commission noted that "the primary content of graduate education for comprehensive care should consist of medicine, psychiatry, pediatrics, medical gynecology, and preventive medicine," "simple rotation will not be sufficient," and "the teaching should stress continuing and comprehensive patient responsibility rather than the episodic handling of acute conditions in the several areas." Since then, an increasing number of publications has called for a national commitment to the education of personal, family, or primary physicians at all levels of training. These include a later report by Millis (6), the Carnegie Commission report (7), and articles by Willard (8), Haggerty (9), and McGraw (10).

The historical background and problems of the developments in primary care have been thoroughly reviewed by Alpert and Charney (11), who are pediatricians. These authors also described past and current undergraduate and graduate medical education programs as well as the elements of a successful primary care program. A psychiatrist reading this monograph will agree with many of their observations and conclusions.

With this demand for primary care providers increasingly articulated by the public and likely to be expressed in legislative mandate, certain forces are emerging that favor the integration of "scientific medicine" and "psychological medicine." These forces include a definition of primary care that focuses on the patient more than on the illness, the interface between patient and doctor, acceptance of the psychological aspect of care along with the physical and social, and recognition of longitudinal responsibility for the patient (11). We may note that the focus on the interface between patient and doctor is identical with that on the patient-physician relationship described by Deutsch and associates (1).

Training programs designed to meet some or all of these goals are attempting to grapple with specialty separatism and the long-standing constraints in the teaching hospital and the medical school (12, 13). The following facilities and capabilities would help to provide a supportive environment for the mastery of psychological medicine: an ambulatory in addition to a crisis-oriented inpatient setting, training programs that last for several years and are centered in hospital outpatient departments and neighborhood health centers, selection at all levels of trainees who have an interest in primary care, and a multidisciplinary faculty, including psychiatrists.

My experience in this field, in addition to more than 10 years of teaching medical students and both psychiatric and nonpsychiatric residents, has been as a teacher for 2 years in an innovative primary care residency training program in pediatrics and medicine at Boston City Hospital. Under the joint direction of Joel J. Alpert, M.D., Chairman of the Department of Pediatrics at Boston University School of Medicine and Chief of Pediatrics at Boston City Hospital, and Alan S. Cohen, M.D., Chief of the Department of Medicine at Boston City Hospital, this program has been developed as a 3-year track for internists and pediatricians chosen from their overall internship and residency training programs at the hospital. The ambulatory component is housed in a Primary Care Center in the medical outpatient department, with training at two neighborhood health centers as well. The program (which will be more fully described in subsequent works) has a faculty that includes internists, pediatricians, psychiatrists, nurse practitioners, sociologists, social workers, and family health workers. The trainees are in the clinic 1–3 times a week and follow most of their

patients throughout their training period. A comprehensive built-in evaluation of the program, trainees, patients, charts, and faculty has been developed to assess achievement of the program's aims. Methods for teaching psychological medicine include observation and supervision of work with individual patients, case conferences, and seminars similar to those outlined by Deutsch and associates (1), Balint (14), Reichard (2), and others.

What is new for liaison psychiatrists is the combination of the new emphasis, the recognition of past and current problems confronting medical education, the developing institutional support, and the longitudinal training aspect, which includes the involvement of the psychiatrist. To quote Alpert and Charney (11),

> the primary care doctor spends most of his time thinking about the patient and the impact of various forces on his health or illness over a period of time. The secondary or tertiary level doctor spends most of his time thinking about a disease state or a technical skill and how various patients fit into or alter that field of interest over a period of time. For one, the illness is the episode; for the other, the patient is the episode. (p. 3)

Previous programs for both medical school and house staff training in general have emphasized block, short-term experiences at the expense of longitudinal ones. The longitudinal aspect in such a program as the one described above allows for the overwhelming experience of the internship and the intern's need to master "desperate medicine" (15), while providing an early opportunity for "imprinting" or identification as a future primary care physician. As the intern rises from the nadir of his receptivity to psychological learning to a less anxiety-filled residency, the psychiatrist, along with the other primary care faculty members, is still there to help him master his broader task. To quote Alpert and Charney (11) again, "The student is most likely to learn how to elicit, to appreciate, and to utilize social and psychological data when the curriculum permits long-term contact and responsibility for some patients, and when the setting prompts him to consider such problems as pertinent" (p. 60).

The mutual student and faculty selection process at medical school and internship levels may result in a greater proportion of trainees who are open to the idea of a continuum in physiological and psychological medicine rather than a dichotomy. The process by which program and trainee select each other can include a mutual selection interview such as that which improved the success of the teaching of the Balint group (3).

Since 1966, when the Millis Commission Report called for a national commitment to produce primary care physicians who would represent for most patients the common point of entry into a reorganized, revitalized, and rational system of health care delivery, certain traditions in medicine have come under increasing scrutiny and pressure to change. Primary care medicine may be a major vehicle for overcoming the traditions that maintain the mind-body dichotomy. A careful evaluation of this aspect in such training programs will help us to answer the question posed in the title of this paper.

Student Mental Health Services and Departments of Psychiatry

BY CLIFFORD B. REIFLER, M.D., M.P.H., AND RAYMOND BABINEAU, M.D.

The authors suggest that the potential usefulness of a college mental health service as a site for teaching, training, and research has been underestimated by departments of psychiatry. College health services can provide an opportunity for both trainees and investigators to deal with concepts of psychotherapeutic intervention, a developmental perspective, and a community mental health orientation.

A RECENTLY PUBLISHED STUDY of psychiatric residency programs reviewed a broad range of clinical interests and training loci in current residency programs (1). We note, however, that college mental health services were not mentioned in the survey. We believe this would be a useful time to reemphasize the potential merits of a close affiliation between a psychiatry department's residency training program and a college mental health service.

Relationships between departments of psychiatry and student health services have shown considerable diversity. On one hand there are educational institutions with well-developed and established programs in both psychiatric residency training and mental health services for students in which the two facilities seem to operate on entirely separate tracks in splendid isolation from the interests and needs of each other. For many years the University of Michigan was one of the better examples of schools with this arrangement. Just across Lake Michigan, on the other hand, is an outstanding example of a quite different model. At the University of Wisconsin the entire responsibility for providing student psychiatric services is taken directly and apparently exclusively by the department of psychiatry without any significant association with the student health service. One of us (C.B.R.) has been fortunate in having been associated with institutions in which neither extreme exists. Both the University of Rochester and the University of North Carolina follow a model of joint appointments, shared responsibility, and common endeavor.

Institutions in which the possibility of joint contributions exists have developed overlapping interests and activities to a varying extent. Unfortunately, the possibility of such collaboration is not always present. Although there are more than 2,000 institutions of postsecondary education in the United States, there are only 114 medical schools, 99 of which have psychiatric residency programs affiliated with them. Of the medical schools with psychiatric programs, almost half either have no university affiliation (e.g., Rush Medical College in Chicago) or are located on a medical center campus separated from the parent university. This distance may be no more than a few miles (e.g., New York University in New York City), or the two campuses may be separated by an entire state (e.g., the University of Oregon, which has its medical school in Portland and the main campus in Eugene). These geographic and organizational relationships influence many aspects of the medical school's functioning, including health care.

Even when medical centers are independent of or geographically separated from a university, they encompass broad teaching programs in allied health fields and therefore have a responsibility for the health needs of substantial numbers of students. The degree of acceptance of this responsibility for the health needs of their students varies considerably among medical centers, in terms of providing for general health care and mental health needs. There are no extensive data on how well this responsibility is being met, but a field study sponsored by the Joint Information Service of the American Psychiatric Association and the National Association for Mental Health gave an in-depth view of 7 different models of mental health delivery systems to students (2).

As we view how medical centers handle their responsibility for the health care needs of a variety of students (including medical and nursing students, graduate students in biomedical sciences, and students in X-ray or laboratory technology), we have the impression that it sometimes happens that these students suffer from benign neglect. It is assumed that because of their proximity to a medical center, they will find access to health care. The degree to which this neglect is a problem is undocumented.

There have been no national surveys of mental health resources in colleges and universities since that of Gundle and Kraft in 1953 (3), which did not specifically deal with medical centers. They surveyed 1,000

Revised version of a paper prepared for a workshop at the Conference on Psychiatric Education commemorating the 25th anniversary of the Department of Psychiatry, University of Rochester, Rochester, N.Y.

Dr. Reifler is Director and Dr. Babineau is Chief, Mental Health Section, University Health Service, University of Rochester, Rochester, N.Y. 14642. Dr. Reifler is also Professor of Health Services, of Psychiatry, and of Preventive Medicine and Community Health and Dr. Babineau is also Associate Professor of Psychiatry, University of Rochester.

colleges and universities and found well-developed student mental health clinics in 101. At that time only 8 facilities reported involvement with psychiatric residency training programs. In the more than two decades since that survey, both residency training programs and student mental health programs have proliferated, and there has been increasing recognition of areas of common interest and mutual involvement.

EDUCATIONAL CONSIDERATIONS

An important educational consideration is that health professionals in training are influenced by the model of care they receive. With specific reference to mental health services, the attitudes of future physicians and other health care professionals are strongly influenced by the quality of the help received or not received and the role models they see in a health service. For example, it is not unusual for a college student or a medical or nursing student who has been significantly helped by a psychotherapeutic intervention to begin to think seriously about a career in a mental health field or to view the field in a more positive way.

In psychiatry departments in which the opportunity exists, the student health service has long been recognized by psychiatric residents as a popular rotation that is sought and anticipated, whether elective or required. This has also been true of graduate students in psychology.

With respect to needs for psychiatric clinical education and training the reasons for the student mental health service's popularity are clear. Patients with psychiatric problems who come to a student health service are usually seen within a few days after their request for an appointment. Their distress is fresh, their problems are often of recent development, and there has not been time for affect to be discharged, either by multiple screening interviews or by accommodation to an elevated level of anxiety. The patient's contact with the center is often the first such experience he or she has had; the illness can therefore be seen in the early phases of development.

The student patients are generally young, intelligent, and articulate. They are often extremely verbal and able to express their thoughts and feelings in a manner the resident can understand. Many of the student patients are well motivated and responsive to psychotherapeutic intervention. Most of them get better, and they often show a positive response in a relatively short period of time.

It is an important experience for the beginning therapist to see that psychotherapy can bring about change. One of the frequently mentioned difficulties of current residency programs is that of identity diffusion and therapeutic nihilism (4, 5). Successful therapeutic experiences with student patients are useful for validating the psychotherapeutic process. They also serve to provide the beginning therapist positive feedback regarding the utility of his or her own activity.

Another important characteristic of the college mental health service is that it provides the resident an opportunity for exposure to an increased range of psychopathology, primarily in the direction of normal behavior. The experience also provides the resident a singular opportunity to make use of a developmental perspective in understanding human behavior, particularly the tasks of late adolescence and early youth.

An example of the health service's role in focusing on a developmental perspective was described at one of our weekly mental health staff training conferences. Five third-year residents were reviewing their experience working during the past year in the student health service. One resident commented that before this experience the pedagogic injunction to "view your patients in a developmental perspective" had often been a meaningless cliché for him. Working with students, however, had taught him the meaning and utility of this concept. He had learned that he could not have a good clinical understanding of a freshman student unless he knew how the student was faring with the developmental tasks of separation, adjustment to a new environment, and adaptation to social and academic pressures. Similarly, in dealing with college seniors he had learned to be clinically inquisitive about such issues as readiness for postgraduation life and comparison with peers concerning levels of academic, social, and sexual achievement.

None of the preceding is meant to imply that severely disturbed people are not seen at a student mental health service; the incidence of acute psychotic disturbances is fairly uniform: 2 per 1,000 university students per year (6). However, there are few other clinical facilities that offer an opportunity for the same degree of careful study and observation of persons functioning at the normal to neurotic end of the disability continuum.

There are also few other populations in which the relationship between socioenvironmental stress and the development of psychiatric symptoms is as clearly manifested and as potentially amenable to planned interventions. The responses of students to such factors as changes in their living conditions or in the curricular or social structure can often be readily identified clinically and are available for systematic study in the college community (7).

THE UNIVERSITY COMMUNITY

We have thus far discussed the collaboration of departments of psychiatry and student mental health services in the care of those who are identified as patients. This is the central core of the activity of a college health service and is an important clinical function of a department of psychiatry.

However, educational and service needs extend beyond the identified patient into the community, in this case, the well-defined university community. As articulated previously (8, 9), the college-community

interventions of a college health service can be used as both a model and a laboratory for studying and evaluating many aspects of community psychiatry.

Using this opportunity most effectively is usually difficult, even for a well-staffed college health service. The varied professional skills necessary to do so are often beyond the scope of a self-contained health service and are more likely to be found in a health service with a close affiliation with a department of psychiatry. Optimally, mental health professionals in a health service should have academic appointments with teaching and research responsibilities. Unfortunately, research and scholarly inquiry have not frequently been the hallmarks of college mental health services. Encouragement and collaboration in these endeavors is an area in which a department of psychiatry can make a profound contribution to both psychiatry and college mental health. In doing so, the department offers its residents and other mental health trainees a useful training locus where concepts of psychotherapeutic intervention, a developmental perspective, and a community mental health orientation can become quite real and well integrated.

Early Sex Education in Relationship to Later Coital and Reproductive Behavior: Evidence from Jamaican Women

BY EUGENE B. BRODY, M.D., FRANK OTTEY, M.D., AND JANET LAGRANADE, M.D.

In a group of 150 working-class Jamaican women, lack of information from their mothers about sex coupled with chronic resentment was associated with having had more sexual partners, impregnators, and children. In contrast to age at first coitus, age at first pregnancy did not seem related to the early availability of information about sex, and it was less significantly correlated with overall education.

ALTHOUGH THE IMPACT of early experience on later sexual and reproductive behavior is a matter of great interest to psychiatrists, most studies in the field are essentially anecdotal and limited to a small number of women who have presented themselves as patients with emotional difficulties. However, the occurrence of pregnancy in adolescents and of unwanted pregnancy in general is attracting systematic research interest.

Some studies of pregnant adolescents in the United States have elicited histories of inadequate sexual education and reproductive-contraceptive information and ambivalent and conflictful mother-daughter relationships (1–4), as well as insufficient parental supervision in general, with a relative lack of reinforcement of conventional ethical codes (5). Promiscuity and failure

to use contraception in a purposeful way seem to characterize adolescent girls whose parents were hostile and distant from each other, who felt alienated from their mothers, and were, in contrast, intimate with their fathers (6, 7). The low self-esteem and unresolved dependency needs in girls with such backgrounds are interpreted as reducing the likelihood of their assuming responsibility for their own sexual and contraceptive behavior; these factors also raise the possibility that some of their sexual behavior leading to pregnancy is symptomatic (8). These findings are congruent with those indicating that women who perceive themselves as high on a cluster of competency traits and who have relatively high self-esteem tend to have fewer children than those perceiving themselves as low in this cluster (9, 10).

Several other studies have indicated that failure to use contraceptives, especially among women seeking abortion, is correlated with particular personality traits. They did not, however, report data on the early sex education of the subjects. Kane and associates (11), in fact, have presented information from a group of white women arguing against the idea that lack of information about contraceptives contributes to the occurrence of unwanted pregnancy. In another study (12) they found that knowledge of contraceptive techniques was well diffused in a mixed population of black and white women seeking abortions in a small town in the rural South.

The lack of systematic data on this score, as well as clinical evidence that parents' willingness to offer sexual information to their children is an indicator of the nature of the developmental setting, directed our attention to the problem. The present report is based on data gathered during the course of a larger investigation of psychocultural influences on contraceptive behavior in Jamaica (13). This is a country in which, traditionally, early demonstrations of fertility are highly valued, at the same time that a pattern of "strictness" and failure of mothers to give formal sexual instruction to their daughters has been noted for a generation as a problem related to family life (13–16). This failure of intergenerational communication exists in a matrifocal familial setting (17) in which the centrality of the mother-daughter relationship influences the attitudes of both to men, sex, and reproduction; it creates a situation in which a woman sometimes is more responsive to her mother's needs and wishes than to those of her mate (13). With these considerations in mind, this report presents data, obtained through life-history interviews, relating early sex education from parents (or surrogates) to later sexual and reproductive performance in Jamaican women.

THE STUDY POPULATION

We studied 150 women residing in Kingston, Jamaica. The sample included 100 female clients (all contraceptive users including 12 who were just beginning to use them) at the Jamaica Family Planning Association clinic in the inner city and 50 female patients, nonusers of contraceptives, at a comprehensive health center serving a comparable population. Each woman was interviewed for approximately 2½ hours in the setting where she had come for help. Subjects were selected at random by the clinic or center nurse as the interviewers were available. These last, Jamaican psychiatrists trained by the senior author, used an associative clinical interview style, following leads as the patients offered them. Data were recorded on forms outlining detailed life history including sexual, contraceptive, and reproductive data. If areas were not covered or questions about them were inconsistently answered, the interviewers refocused on the topic in question until they were satisfied that adequate information had been obtained.

Selected as part of a study of fertility-related behavior, the subjects provided a range from early to late contraceptive use to nonuse. They ranged in age from 16 to 47 with a median of 25.5 years; 83.4% were 31 years of age or less. They had had from 0 (12%) to 10 pregnancies each, with an almost even division between 0–2 and 3–10. Forty percent had been pregnant by 2 or more men.

The status of their relationships with their current male partners approximated that of the population at large: 84% had never been legally married; 43.3% were visited regularly by a man for the purpose of sex, companionship, or child rearing; and 48.7% cohabited with their current mate, including 34% in a common-law relationship and 14.7% who were legally married. In almost one-half of the cases the current relationship had not continued for more than 3 years.

More than three-fourths of the women had never received any information about sexual relations from their parents or surrogates, and almost one-half had had no adequate instruction about sex or reproduction from anyone prior to menarche. Approximately one-third had not received such instruction prior to the birth of their first child or by the time of the interview. Over one-half expressed resentment at their mothers for their failure in this respect, and for another 14% the resentment was easily inferred. More than two-thirds also reported experiencing strong negative feelings (shame, disgust, and fear) at the onset of menstruation. Only 8.7% had clearly positive feelings about becoming a woman.

Almost one-half (46.7%) had had intercourse by the age of 16, and two-thirds by 17. Only 5.7% had used contraception on this occasion, and for 10% first intercourse resulted in pregnancy.

Over three-fourths of the women had not progressed past primary school, and 21.3% were illiterate. All but a negligible number had completed their schooling. Of the 66.3% who were employed at least part-time, approximately one-half were in manual jobs (predominantly domestic, custodial, and factory work) and one-half in nonmanual jobs (predominantly low-level clerical work).

RESULTS

The analyses are presented in the form of gammas, coefficients of correlation useful for dealing with phenomena that are not always ranged along a scale in monotonic units and that do not always occur in the form of a normal distribution curve. Gamma measures the predictability of order on one variable from order on another (18). Correlations of .30 or above are regarded as having practical significance. Those of .30 to .20 show valid trends, with decreasing significance. Comparisons with Kendell's rank correlation coefficient suggest that values of .25 to .40 range from probabilities of occurrence of .05 to .001.

Table 1 shows that women who received sexual information from their mothers were older at first coitus (although not at first pregnancy) and had given birth to fewer children by the time of their clinic visit than those who had not had such sexual instruction. Early sex education, regardless of source, was also associated with lower reproductive performance and fewer sexual relationships, although not with age at first coitus (see table 2). Conversely, more impregnators and more babies (although not age at first coitus or at first pregnancy) were correlated with resentment at lack of information from or communication with the mother about sex, sufficient to permit its expression to interviewers (see table 1).

Table 3 shows a number of positive correlations, of varying significance, between a complex of factors associated with socioeconomic status and modernity and a tendency to be older both at first coitus and at first pregnancy. The correlation between education and age at first pregnancy was much weaker than that between education and age at first coitus.

Being older at first coitus and at first pregnancy appears to have predictive implications. Both factors were correlated with consistent current use of contraceptives and discussion about contraception with current mate, i.e., indicators of conscious communication and planning about personal fertility control.

The role of schooling in this predominantly undereducated population is further explicated in table 2. Greater educational achievement was positively related both to having received sexual information from the mother and to having such knowledge at an early age. As expected, it was correlated with higher age at first coitus, planned and consistent current use of contraceptives, and discussing contraception with a current mate of higher occupational status. While women of lower educational achievement tend to have had more pregnancies by several men and more births, in our sample educational level was only weakly correlated with age at first pregnancy.

DISCUSSION

This group of Jamaican women from lower social classes was characterized by little early sex instruction, poor communication with parents, and an unstable household situation with legal marriage as the exception. Within this group lack of information from the mother about sex coupled with chronic reactive resentment was associated with having had more sexual partners, more impregnators, and more children. Chronic and conscious resentment may follow a complex of childhood factors associated with lack of open communication with parents, or it may be secondary to the unhappy life experience implied by a series of impermanent sexual relationships resulting in cumulative responsibility for child care. Higher educational achievement and having received sex information from the mother were associated with later age at first intercourse, fewer sexual partners and impregnators, and fewer children. We suggest that women with this background were more autonomous, independent, and inclined to self-regulation than most of their island confreres, who left their reproductive functions to chance or nature or, following traditional norms, subscribed to the value of large families.

In contrast to age at initial coitus, age at first preg-

TABLE 1
Correlation Between Sexual Instruction and the Coital-Reproductive Histories of 150 Jamaican Women

History	Correlational Index (gamma)		
	Resents Lack of Information from and Communication with Mother about Sex	Received Information about Sex from Mother	Received Early Sex Instruction Regardless of Source
More pregnancies (versus median or fewer) per age group	.33	−.31	−.09
Number of impregnators in women having 2 or more pregnancies*	.31	−.38	−.22

Uses reliable (oral) method of contraception	.22	.22
Occupational status of mate	.20	.18
Number of impregnators in women having 2 or more pregnancies*	−.20	−.35
Receives significant financial support from mate	−.01	.07

* N=101.

nancy did not seem to be related to early sexual information, and it was less significantly correlated with overall education. Other evidence (13) suggests that this may be due in part to a culturally reinforced wish across social class boundaries for an early demonstration of one's fertility; it may also reflect a relatively low frequency of intercourse at early ages.

Assessment of Sociolegal Judgment of Offenders

BY MARIE S. CERINO, A.C.S.W., AND ANTONIO J. DY, M.D.

While working with young male offenders the authors developed a scale to assess sociolegal judgment, i.e., the ability to evaluate the possible social and legal consequences of various choices of action in a given situation. They found that some inmates had committed crimes because of poor sociolegal judgment, whereas others understood the consequences of their actions but chose to act illegally despite this knowledge.

SOON AFTER WE were given the responsibility in August 1974 of doing diagnostic evaluations on sentenced inmates at a correctional institution for young men (ages 16 to 21) we learned that the traditional mental status examination used by psychiatrists generally failed to evaluate adequately an area that we called "sociolegal judgment." Sociolegal judgment may be defined as the ability to assess the possible social and legal consequences of one's choice of action in a given situation. We assumed that a person who had sound sociolegal judgment and acted in accordance with it would be less likely to get in trouble with the law than someone with poor sociolegal judgment. A notable exception, the person who understands the consequences of different actions and can give an excellent or impeccable verbal description of them, but who still chooses to act injudiciously, will be discussed later.

In the course of sharpening our evaluation process we developed a tool to help measure more objectively various factors believed to contribute to the path to incarceration. This tool, the Multi-Area Review, Interview, and Examination Evaluation (MARIEE) profile (1), provided a graphic representation of inmate strengths and weaknesses, greatly sharpened our evaluations, and countered the "charm" of some of our more manipulative clients.

THE MARIEE PROFILE

The MARIEE profile consists of questions covering the preincarceration, incarceration, and projected postrelease phases of the inmate's history. Areas initially included in the preincarceration part were family stability, parenting, history of socialization with peers, school adjustment, attainment in school, impulse control, violence, drug and alcohol use, juvenile record, adult criminal history, psychiatric history, and employment history. The incarceration section assessed family stability and support, current educational involvement, vocational training, adjustment in the institution, and psychiatric functioning. Items in the projected postrelease section included marketable skills, residence, and supportive people.

Although the preincarceration and incarceration profiles provided fairly clear pictures of the many possible reasons why most inmates had gotten into trouble and the changes that had occurred in them since incarceration, they failed to clarify why some inmates with high scores in most areas had become involved in criminal activity. As we interviewed more of these atypical inmates we began to sense that a crucial dimension was missing from the profile. When the sociolegal judgment scale was introduced the puzzling profiles became more comprehensible. This scale was placed between the preincarceration and incarceration phases because it deals with both present judgment and previous behavior.

THE SOCIOLEGAL JUDGMENT SCALE

The test to measure sociolegal judgment was devised after we had considerable experience with a number of inmates who seemed to have incurred incarceration more because of lack of judgment in handling a situation than because they had intended to commit a crime. The scale's questions may be grouped into 4 categories: offenses or situations involving 1) acquisition, 2) circumstantial or peer involvement, 3) violence, and 4) sexual involvement. The questions themselves are given in appendix 1.

Ms. Cerino is Coordinator, Diagnostic Evaluation Unit, Connecticut Correctional Institution, Box G, Cheshire, Conn. 06410. When this paper was written Dr. Dy was Assistant Professor of Psychiatry, Yale University, New Haven, Conn., and Consulting Psychiatrist, Department of Correction, State of Connecticut; he is currently Associate Professor of Psychiatry, University of Hawaii, and Chief, Diamond Head Community Mental Health Services Branch, Honolulu, Hawaii.

The conclusions and opinions expressed herein are those of the authors and do not necessarily reflect the views of the State of Connecticut Department of Correction.

The inmate was asked what he would do in each given situation and the reasoning behind his choice of action. It was sometimes helpful to further elaborate the hypothetical situation to get a clearer picture of the subject's apperception, evaluation, decision, and reaction. Scoring was done on a 7-point scale (+3 to −3) similar to the scale used for the other variables on the MARIEE profile (see appendix 1).

DISCUSSION

The inmate who gives a perfect verbal response on the sociolegal judgment scale but has committed a series of offenses obviously presents a special problem. We generally recognize, however, that he may be a bright "sociopath" who knows what is right and wrong but chooses, in spite of this knowledge, to advance himself by illegal means and is then caught.

Warren and associates (2) described a classification of interpersonal maturity levels for juveniles that takes into account some of the same factors as our sociolegal judgment scale. For example, a person at one of the lowest maturity levels (I_2) in that system "is primarily involved with demands that the world take care of him" and "is not interested in things outside himself except as a source of supply." A person who is at the I_2 level on Warren and associates' scale is likely to score −3 on our scale.

From our contacts with incarcerated offenders, we have noted that there is a small group whose main problem is a genuine difficulty in sizing up a situation and responding to it appropriately. These inmates seem to suffer from poor judgment, which might be repaired with sociolegal counseling. Through use of the sociolegal judgment assessment scale, we have become more able to recommend therapeutic approaches for our inmates, e.g., suggesting individual counseling focusing on a weak point in exercising judgment, or referring the inmate to a program designed along the lines of the moral development theory of Kohlberg and associates, the Just Community Program at the Connecticut Correctional Institution-Niantic (3). This program reported a prison return rate of only 16% for program participants (3, p. 4). However, only female inmates were program participants at the time of the study. If this rate of return is replicable when the program includes men, it would certainly be an improvement over the general return rate of approximately 33% at the facility for male youth (4).

In addition to helping us make referrals to the Just Community Program, the sociolegal judgment scale also guided us in making referrals to the Oncit Program (an intensive treatment unit at the Connecticut Correctional Institution-Cheshire that is run as a therapeutic community) and the Thresholds Program (a decision-making course run by volunteers at the Connecticut Correctional Institution-Cheshire).

One of us (A.J.D.) has also begun to use this assessment on adult male offenders. We hope that additional applications by ourselves and others will contribute to the refinement of this assessment tool.

APPENDIX 1

The Sociolegal Judgment Scale

QUESTIONS

Acquisition

1. If you saw a friend taking the tires off a car and he asked you to stand on the corner and alert him if the police were coming, what would you do?
2. If you found an envelope addressed and stamped but open, and inside found a letter, a photograph, a check, and some cash, what would you do?
3. If someone wanted to sell you a color TV for a lot less than you knew it was worth, what would you do?

Circumstantial Involvement

1. If a friend offered to pay you to keep a box for him because he was going away for a few weeks, would you do it?
2. If you were at a party while on parole or after discharge and people were drinking liquor and smoking pot, what would you do?

Violence

1. If you came upon a friend in the street and he was having a fight, what would you do? If it were two against one?
2. If you were at a party, or on the street, and people started throwing banana peels at you, what would you do? If you were hit with a bottle? If they were throwing garbage cans?
3. If someone were breaking into your home what would you do? If a phone were available? If a gun were available?

Sexual Involvement

1. If a young girl (of uncertain age, maybe about 15 years old) became very friendly with you at a party and asked you to go off with her, would you do so?
2. If, while you were delivering something to homes, a woman asked you in for coffee, would you stay? If she were in a negligee?

SCORING

+3: congruence of positive verbal sociolegal judgment with behavior; value system internalized.

+2: general but not consistent congruence of positive verbal sociolegal judgment with behavior; value system externalized and focused on the legality of the behavior.
+1: general but not consistent congruence of positive verbal sociolegal judgment with behavior; value system externalized and focused on not getting caught.
0: positive verbal sociolegal judgment, but not supported by previous behavior or value system.
−1: fair verbal sociolegal judgment; some minor inconsistencies within categories.
−2: poor verbal sociolegal judgment; some major inconsistencies, maybe in more than one category.
−3: extremely poor verbal sociolegal judgment borne out by behavior that is mostly self-aggrandizing or self-gratifying.

Journal Policy on Multiple Authorship

It has come to our attention that there has been some misunderstanding regarding the *Journal's* policy on polyauthorship. The number of authors listed on a paper is not a factor in the review and acceptance/rejection procedure. However, once a decision has been made to publish a paper, we do apply *Journal* policy regarding the number of authors in the by-line: only principal researchers and writers of articles are listed in the by-line; collaborators who have provided technical and other assistance are acknowledged in a footnote. In papers that list more than 4 people as principal authors, we query the first author to verify that those individuals were substantial contributors to the research or ideas reported. Since certain types of psychiatric research may require multiple workers, we will of course include all of the names in these cases.

LETTERS TO THE EDITOR

Lithium and Depression

SIR: The excellent article "Overview: Maintenance Therapy in Psychiatry: II. Affective Disorders" by John M. Davis, M.D. (January 1976 issue) raises the issue of the treatment of depression with lithium, which aroused controversy for many years. Although data from uncontrolled studies have been conflicting, there is an emerging consensus from controlled studies that lithium *is* effective in the treatment of depression, with a greater likelihood of response expected in patients with bipolar illness, recurrent depressions, and a family history of affective disorders (1, 2).

Over the past several years I have observed phenomena in some bipolar and unipolar depressed patients which suggest that the achievement of adequate plasma lithium levels should be more carefully considered in these evaluations. Three bipolar patients in manic phases responded to lithium at plasma levels of less than 1.0 mEq/liter, first with an abatement of their manic symptoms and then with the emergence of a significant depression that was relieved in all instances by increasing the lithium dosage until a plasma level of greater than 1.0 mEq/liter was reached. Because of mild gastrointestinal symptoms, the lithium dosage for one of these patients was reduced by 300 mg/day, with a prompt return of depressive symptoms. The patient's serum lithium level was 0.8 mEq/liter at this time. Restoration of the additional 300 mg of lithium/day resulted in a rapid improvement of symptoms and a lithium level of 1.1 mEq/liter.

These data suggest a biphasic response of bipolar manic-depressive illness to lithium in some patients, with the depressed phase requiring higher plasma lithium levels (often greater than 1.0 mEq/liter) than the manic phase. This possibility needs to be evaluated carefully because of its obvious therapeutic and theoretical implications.

In four unipolar depressed patients, therapeutic results were also not observed until serum lithium levels greater than 1.0 mEq/liter were achieved. In one patient whose illness had been under good control with lithium for three months, a return of symptoms was noted to be related to an alteration in dosage by the patient from 300 mg four times a day to 600 mg twice a day. Symptoms were relieved by a return to the original dosage pattern, which suggests an extremely sensitive relationship between therapeutic response and lithium steady-state blood levels in this patient.

In my experience, in addition to the two variables noted above, other factors may also be useful in predicting which unipolar depressed patients are likely to respond better to lithium than to tricyclic antidepressants. The most common of these are increased sleep and appetite associated with the episode of depression and a transient period of a few hours to several days of feeling better than usual (athough not to a degree that could be classified as hypomanic), immediately followed by significant depression. These clinical impressions are in partial agreement with the findings of Kupfer and associates (3).

It is my opinion that the group of "unipolar" patients who respond best to lithium actually have a variation of bipolar illness (bipolar III?) in which the manic and/or hypomanic phases are not expressed clearly.

Editor's note. The reader is referred to the article by Ronald R. Fieve, M.D., and associates earlier in this issue for more on this topic.

The Psychiatrist as an Expert Witness

SIR: The psychiatrist who testifies in court must accommodate to the roles and procedures of that system. He must cope with the criticism of peers who say that the psychiatrist has no place in the courtroom. I feel that this criticism is misdirected and results from a lack of understanding of our legal system and misconceptions regarding the role of expert witnesses.

In court, opposite sides allege different circumstances. The judge guides the proceedings in order to make relevant information available to the jury while keeping out prejudicial or inflammatory statements. The jury, which represents society at large, considers the evidence and reaches a decision. Additionally, in criminal cases, the jury is given a standard proof. The decision is not to be made by preponderance of evidence or with reasonable certainty but must be beyond a reasonable doubt. Ordinary, or fact, witnesses tell what they have seen; psychiatrists and other expert witnesses are allowed to express opinions. The adversary nature of our system of justice allows and requires each side to try as diligently as possible to introduce all favorable evidence and to suppress all unfavorable evidence. The goal of this process is justice, not truth.

The expert witness is allowed to express an opinion on matters beyond the knowledge or experience of the ordinary person. The judge designates a person as an expert witness in a particular field after hearing evidence that the individual has special training or experience. The expert witness is then allowed to express an opinion based upon application of his special knowledge to the facts in evidence.

The role of the expert witness is to assist the jury in consid-

ering a broad range of explanations, not to make the decision for the jury.

The expert witness is subject to cross-examination or challenge by the opposing side to ensure that his credentials as an expert are valid, that his opinion is well-founded, that his examination of the issues was adequate, and that his opinion does not go beyond the limits of his expertise and the facts that are available. Correspondingly, the advocate calling the expert witness seeks to validate and bolster his opinion.

Some psychiatrists serving as expert witnesses may fail to perform a proper examination, may reach unsound conclusions, exaggerate their testimony, be biased for or against one side, or allow themselves to be unduly influenced. All of these errors represent poor clinical practice, but they do not invalidate the role of expert witness in the legal system.

Those psychiatrists who do not understand the function and operation of the civil/criminal justice system or who find the ground rules and procedures not to their liking may choose to avoid participation. In my judgment, however, the psychiatrist who is skilled in understanding the legal issues, making an appropriate assessment, and putting forth his views has a valid role in the courtroom as an expert witness. He must be prepared for challenge and criticism, keeping in mind the function of his role—to provide a valid opinion, not to decide the issue.

Behavioral Theory in Psychiatric Education

SIR: Two articles in the *Journal* (1, 2) have outlined some proposals for specifics of psychiatric residency training. Although it is certainly true that the primary focus of such training should be the development of skills that enable the graduate psychiatrist to *do* psychiatry, it seems desirable that one should be familiar with the theoretical bases of one's activities. In perusing these articles I noted that a broad area of information, basic behavioral theory and research, was significantly underemphasized or not even acknowledged. Langee and associates (2) defined five categories of "what the resident needs to know," including among others "theories of individual psychological personality development" and "the biological determinants of behavior and emotion." However, they neglected the equally important need to know the basic psychological or behavioral determinants of behavior and emotion that in many cases form the theoretical underpinnings of those theories of personality development and behavior. One may counter by proposing, as has Baum (3), that a psychoanalytic core in resident education serves this purpose admirably. This may be true, but other areas of behavioral theory, including basic experimental psychology, have made and continue to make contributions to all fields of psychiatric knowledge, from behavior modification and biofeedback to the experimental analysis of group process. Drs. Yager and Pasnau (1) seem to be aware of the need for this type of instruction, but the emphasis in their paper is elsewhere.

The import of the body of behavioral knowledge is recognized by some. Freedman and associates devoted almost 5% of the total text of the *Comprehensive Textbook of Psychiatry* (4) to behavioral science. I wonder if others around the country who are designing and teaching residency programs are including this fundamental area. If they are not, shouldn't they be?

Chronic Callers to a Crisis Center

SIR: The Honolulu Suicide and Crisis Center is primarily a telephone service manned by trained volunteers. Psychiatric consultants are available during the hours when the mental health centers are not open, as are outreach teams that can be sent out by the consultants. During the center's six years of operation, we have identified three major types of callers: the bona fide suicide and crisis caller, the crank caller, and the chronic caller. I would like to describe the chronic callers, who fall into five subtypes.

1. Individuals with chronic or recurrent crises that do require repeated intervention or suggestions.

2. Individuals with chronic or recurrent crises that the trained volunteers do not seem to be able to help. This group includes patients who are probably manic-depressive or unipolar depressives. Some are chronic schizophrenics who have managed to avoid contact with mental health clinics, despite the latters' vigorous outreach programs.

3. Isolated and lonely individuals who need someone to talk to. These people often call three or four times every night and stay on the phone for up to two hours. Some volunteers talk with them generously on slack evenings, while others soon reach their tolerance levels and become annoyed. Some volunteers feel sympathetic; others feel guilty. The volunteer often needs someone supportive and understanding on the staff with whom to discuss these situations. One way to cope with these calls is to tell the caller that he will be given 10–15 minutes to talk about his problems, after which the volunteer will have to terminate the call. We feel that this is better than telling the individual to stop calling, since he/she may at some point have a true crisis. However, we do not want to encourage these people to generate crises in order to call. We are considering organizing evening social clubs in collaboration with other agencies and members of the clergy because we do not think our center can function as a "phone-pal" club for these lonely people.

4. Sex callers who use the volunteers (usually those of the opposite sex) as the objects of obscene phone calls. Our volunteers are usually more annoyed by the inappropriate use of our service than by the behavior per se. Generally, they handle such calls by telling the individual that other more urgent calls have to be attended to. A few volunteers conduct some reality counseling with these people regarding the possible social and legal consequences of this behavior. As is the case with all callers who need treatment, the volunteer offers to help arrange a mental health clinic contact.

5. Alcoholic callers, who usually call after a few drinks. It might be interesting to test the usefulness of having bartenders volunteer to help these callers. At present, a sister agen-

cy (the Volunteer Information and Referral Service of Honolulu) answers for Alcoholics Anonymous after hours and has a list of AA workers to call when necessary.

Treatment of Tardive Dyskinesia with Deanol

SIR: On reviewing the literature on tardive dyskinesia, one is struck by the lack of any definitive treatment for this distressing condition. Recently, deanol has been found effective (1). I would like to describe a case of such treatment.

The patient was a severely retarded 17-year-old girl who received thioridazine in a daily dose varying between 100 and 800 mg for the control of maladaptive behavior. After a little more than 2 years she developed purposeless, writhing, repetitive, involuntary movements of the legs, arms, hands, and neck. She vocalized constantly and her speech had become incomprehensible, her gait was ataxic, and she was falling frequently. She was not eating well and was losing weight. A diagnosis of tardive dyskinesia was made, thioridazine was discontinued, and she was given deanol in a dosage that was increased to 1200 mg/day. A gradual improvement in her condition was noted, although the symptoms seemed to recur if the deanol dosage was reduced. Finally, after a period of 3 months deanol was discontinued with no return of the previous symptoms.

Deanol appears to be a useful drug in the treatment of tardive dyskinesia and should be studied on a larger scale.

Diagnosis and Treatment After CO Poisoning

SIR: "Carbon Monoxide Encephalopathy: Need for Appropriate Treatment" by Roy Ginsburg, M.D., and John Romano, M.D. (March 1976 issue) offers treatment recommendations that all physicians should appreciate.

The authors' suggestion that ECT should be avoided following exposure to CO poisoning is particularly cogent. ECT is commonly associated with a transient amnestic syndrome, and there are reports of ECT's resulting in a recurrence of neuropsychiatric sequelae if it is given within a month of recovery from CO poisoning (1). Electrical treatment should be avoided after CO poisoning (except in emergency situations) because it seems to complicate an ongoing organic process.

The anemia of the patient the authors described was certainly a factor in CO poisoning causing a chronic brain syndrome. The toxic action of carbon monoxide is by two mechanisms. First, the stronger affinity of hemoglobin for carbon monoxide than for oxygen results in what might be considered a "relative anemia." Second, the shift to the left in the oxygen dissociation curve means that oxygen tension must fall to much lower levels before the oxygen is released in the tissues. Thus anemia would result in an even greater degree of anoxia than expected (2), and the neuropsychiatric sequelae would probably be more severe.

The authors stated that diagnosis of this patient was difficult because of her fluctuating, bizarre behavior. Our investigation in this area suggests two points that might aid in diagnostic clarification. A delayed or fluctuating course may be a result of the slow demyelinating process that occurs after severe CO poisoning. Carbon monoxide is known to produce demyelination without significant neuronal damage; this phenomenon has been discussed in the literature as one that mimics psychiatric disease (3). The second fact is that the parietal symptomatology often present in these patients may be falsely diagnosed as hysterical.

Others have suggested that parietal lobe signs in CO poisoning may be more frequent than was thought previously (4). Unilateral neglect and the higher psychosensory and psychomotor phenomena associated with parietal pathology may appear bizarre and can be mistaken for psychiatric symptoms. Critchley (5) stated, "the lack of distress over the existence of a disability may be mistaken for the fatuous euphoria of the hysteric." I urge physicians to be aware that parietal lesions may be found after CO poisoning and that they can easily be misdiagnosed as a hysterical phenomenon.

Putting Ethics Into Practice

SIR: In general, I agreed with the ideas expressed by Fritz Redlich, M.D., and Richard F. Mollica, M.D., in "Overview: Ethical Issues in Contemporary Psychiatry" (February 1976 issue). I would, however, strongly disagree with their statement that "Coercive treatment due to a patient's being dangerous or incompetent must be ordered by a court of law on the basis of evidence of such behavior and the value and availability of the treatment." This statement makes me suspect that Drs. Redlich and Mollica are some distance from general medicine. Psychiatric consultants in community general hospitals engage almost weekly in emergency coercive treatment, both medical and psychiatric, when it is not possible to obtain the permission of the slow-moving courts. For example, I recently participated in the physical restraint of an acutely schizophrenic 31-year-old man who had first- and second-degree burns of the chest. Two days after his intensive and involuntary treatment with haloperidol, he was awake and most grateful for my intervention, and he became a voluntary patient. During the same week, I also helped to care for an acutely ill patient with a cardiac arrythmia and delirium tremens. This patient broke a nurse's sternum while he was delirious, but he was released

from restraint after almost two weeks of delirium and was most appreciative of our coercive therapy. I am sure that this patient would have died had he not been cared for coercively without waiting for the court's permission.

If Drs. Redlich and Mollica agree with the treatment I have described, which I feel sure they do, they should have clearly stated this in their article. In addition to this kind of medical psychiatric problem, one often sees highly disturbed psychotic patients in an acute psychiatric setting, and may fortunately be able to treat them with intensive neuroleptics so that commitment to a state or county hospital is unnecessary; thus the patients are treated without formal consent of the court. In many instances, the patient is in remission by the time his/her case would have come up in court.

I think that in our rush to protect civil liberties we are sometimes denying treatment that patients would want if they were in their senses. I think we must face the fact that as responsible physicians we must sometimes make decisions for our patients and not be carried away by the "myth of total competence." To do so would be to align ourselves with Thomas Szasz and agree with him about the "myth of mental illness." There is a view similar to mine in the same issue of the *Journal* in "Crime and Violence Among Mental Patients" by Arthur Zitrin, M.D., and associates: "To oppose mandatory posthospital care for patients who are known to be at increased risk of dangerous behavior if not supervised is misguided civil libertarianism."

GEORGE A. ROGERS, M.D.
Camden, N.J.

Drs. Redlich and Mollica Reply

SIR: Dr. Rogers' comments address the moral question of how to help control a patient for his own benefit without having established a working alliance or being able to gain his informed consent. In general, coercive treatment in response to a patient's dangerousness or incompetence should be ordered by a court of law on the basis of the evidence of such behavior and the availability of such treatment. Also, coercive treatment should do no harm. However, we recognize that it is often the moral duty of a physician to undertake proper care for a patient in an emergency situation where informed consent is not possible and a court decision is too slow. A severe psychotic depression or Dr. Rogers' patient's burns would necessitate immediate treatment. A physician might even decide on the basis of "caring" in less acute situations to use commitment or restraints to prevent a dangerous situation from developing. The tragic case of the rape and murder of a disorganized woman at a railroad station in Washington, D.C., following the refusal of hospital psychiatrists at St. Elizabeths to treat her against her will highlights this dilemma. It is clear that these psychiatrists might have "broken the law" to help her.

What is obvious in both acute and chronic situations is that clinical responsibility often leads to moral conflict. Whenever a psychiatrist uses either physical or emotional restraints to restrict a patient's freedom without his informed consent, he is definitely in a state of moral conflict, balancing a patient's loss of autonomy and self-esteem against his own duty to care for and help the patient. Whatever the resolution of this dilemma, including the use of supralegal tactics, the physician must be aware of where he is going and why and be fully responsible for the consequences of his decisions. Understanding ethical and legal issues in extraordinary situations leads to increased moral clarity in a physician's everyday practice. Dr. Rogers focuses on moral dilemmas that must be clearly seen as such.

Dr. Rogers also highlights the ethical problems intrinsic to psychiatric consultations, where the psychiatrist is often called upon by his medical colleagues to help "control" a tough case. The consulting psychiatrist is frequently expected to use his pharmacological tools not only to help patients such as Dr. Rogers has described but also to medicate patients who are "troubling" the staff, the doctors, etc. Psychiatric units in a general hospital are often most culpable. Any psychiatric consultation requesting control of a patient's behavior is particularly fraught with moral conflict when the doctor-patient relationship, working alliance, and informed consent have not been developed. It is extremely difficult to exert moral leadership and a sense of "caring" in such situations.

FRITZ REDLICH, M.D.
RICHARD F. MOLLICA, M.D.
New Haven, Conn.

We're Still on the Boards

SIR: In "Experiences of Psychiatry Board Exam Casualties: A Survey Report" (March 1976 issue), Martin R. Lipp, M.D., made several valid points on possible improvements of the certification ordeal. Several of his suggestions deserve close scrutiny by the American Board of Psychiatry and Neurology. For example, I agree with his recommendation that "feedback must be included as an integral part of the examination procedure." Feedback should be given routinely to candidates who have failed the Boards, rather than being supplied only on request. This would help to eliminate or at least reduce any perception by the candidate of a defensive posture on the part of the Board. Also, I feel the success/failure ratios of all residency programs should appear in the *American Journal of Psychiatry* along with the list of successful candidates that is currently published in order to give new residents information regarding the capability of particular programs to prepare their trainees to pass the Boards. This would also enable residency programs to update their selection and training procedures and in the long run would contribute to the upgrading of standards of psychiatric residency education.

I took my Board exams in 1961 and felt that I was treated courteously by the examiners, who seemed to be interested in finding out what I knew rather than what I did not. At the end of the day, I felt that I had been "through the wringer," but I was glad for the experience and felt that I had been treated fairly. I am pointing this out in order to balance the comments cited by Dr. Lipp of six candidates who had failed their Boards.

I have been an examiner more than a dozen times, and I therefore have experiences that may cast some light on the subject of oral examinations. We must recognize that psychiatric interviewing is an intensely subjective discipline; any determination to introduce a dimension of objectivity is doomed to failure because subjectivity is the hallmark of psychiatric practice. We need to realize that making judgments on fellow human beings in our professional practice is a subjective enterprise that may be labeled as capricious, arbitrary, dictatorial, etc. In order to reduce the margin of error, we try to include in the evaluation process the professional experiences of several colleagues and to then formulate diag-

noses, therapeutic programs, etc., on the basis of the consensus thus developed. The same strategy is used by the Board in the following manner.

1. The candidate is examined by an examiner who is not involved in his training and does not know him socially.
2. Candidates are usually examined primarily in areas of their day-to-day professional practice and only peripherally in areas in which they do not have firsthand knowledge.
3. If the examiner does not feel competent in the areas of the candidate's primary interest, he usually disqualifies himself by bringing this fact to the attention of the director of the section, who tries as far as possible to match examiner and examinee expertise. (Each team consists of examiners who are of several different persuasions, although academic psychiatrists do predominate.)
4. There is usually another examiner in the room, and the head of the section drops in during the examination process. Each candidate is thus seen during the hour by two examiners, plus (in most situations) the head examiner. Different examiners' judgments may be contradictory and are therefore pooled in order to arrive at the candidate's final grade. This has been the strategy used by the directors under whom I have worked as an examiner. I am impressed by this system of checks and balances—examiners earnestly dispute and disagree with one another, which gives the candidate a fair chance and increases the margin of safety.

When the written examination was first introduced, these scores were compared with the candidate's grades on the oral examination. I was fascinated to note that there was a strong correlation between these two measures, which gives us some insight into this aspect of the subjectivity-objectivity dichotomy.

I propose that we should have an open debating forum at one of our annual meetings that would include two candidates who failed the Boards, two who passed, two examiners who have actively participated in the examination process, two members of the Board, and two members of the public. If this group actively exchanged ideas (without engaging in finger pointing), we would have a comprehensive perception of Dr. Lipp's concluding question: "In short, what are we doing to ourselves and to one another?"

Kansas City, Mo.

Combining Lithium and Neuroleptics

SIR: "A Placebo-Controlled Study of Lithium Combined with Neuroleptics in Chronic Schizophrenic Patients" by Joyce G. Small, M.D., and associates (December 1975 issue) was a well-done and interesting study. However, although they reviewed the Cohen and Cohen report of irreversible brain damage in patients who received a combination of lithium and haloperidol (1), they placed surprisingly little emphasis on it.

Cohen and Cohen described four patients given a lithium-haloperidol combination who developed similar severe neurotoxic syndromes and went on to have irreversible central nervous system damage (two patients had dementia and dyskinesia and two had only persistent severe dyskinesia). This finding is especially frightening in view of the authors' prior safe experience with this combination in some 50 patients. Although it is poorly understood at this point, the most likely explanation of this finding is a drug interaction between lithium and haloperidol.

Dr. Small and associates advocate the addition of lithium to the treatment regime of certain patients on haloperidol and other neuroleptics. I think that the Cohen and Cohen findings contraindicate the combination of lithium and haloperidol for everyday clinical use until further research can elucidate the exact cause of the syndrome they described.

REFERENCE

JAMES S. BRUST, M.D.
San Pedro, Calif.

Dr. Small and Associates and Dr. Shopsin Reply

SIR: We agree with Dr. Brust that all polypharmacy should be approached circumspectly. His concern about the haloperidol-lithium combination is well taken in light of the report by Cohen and Cohen, which on the surface implicates the combination in producing serious neurotoxic complications. However, their conclusions have since been critically evaluated and found to be rather misleading, serving to alarm the medical profession and possibly to deprive some patients of optimal medical treatment. Data on the safety of combined haloperidol and lithium treatment for appropriately selected and judiciously monitored psychiatric patients have not received the same widespread publicity. These issues were discussed recently in the *International Drug Therapy Newsletter* (1) and have been the topic of several important conferences held by McNeil Laboratories and the Food and Drug Administration (FDA), the proceedings of which have not been publicized. We invited Baron Shopsin, M.D., to coauthor this letter because we felt it essential to describe these official reviews in light of the negative climate that has been generated by the Cohen and Cohen article.

Shortly after the Cohen and Cohen article was published, a seminar on haloperidol-lithium interactions was held at McNeil Laboratories. Outside participants included Drs. Shopsin, Ayd, Mendels, and Tupin. Subsequently, all available data on lithium-neuroleptic combinations, including the Cohens' cases, were reviewed by the FDA. The official position that emerged from the conferences was that the combined use of lithium and haloperidol can continue within the guidelines of added caution suggested by the manufacturer.[1]

Several factors were considered in the FDA decision, including the conspicuous absence of similar reports of irreversible neurotoxicity despite the general use of the neuroleptic-lithium combination throughout the world for more than a decade. Further, careful review of the cases recorded by Cohen and Cohen has led to somewhat different conclusions about their possible etiology. Although the term "irreversible brain damage" was part of the article's title, only two of the four patients continued to show impairment. Two patients manifested tardive dyskinesia, which was present before treatment in one of them. Then, too, this is a *potentially* irreversible condition which is often remediable and which may occur with neuroleptics alone. Two of the cases Cohen and Cohen cited were elderly patients who would be prone to develop neurological and/or

[1]Information is available on request from McNeil Laboratories, Camp Hill Rd., Fort Washington, Pa. 19034.

other medical problems; one of them had suggestive organicity beforehand. Then, too, three drugs should be considered since benztropine was given along with lithium and haloperidol to three of the four patients. Benztropine and similar drugs can induce neurotoxicity (2–5), including toxic psychosis (6). Moreover, long-lasting neurological impairment (7) and even death (8) can result with either lithium or haloperidol alone.

A diagnosis of schizophrenia might have been more appropriate than manic-depressive illness for the Cohens' patients. Acute schizophrenia is considered to be a relative contraindication for lithium, although our report would suggest that in carefully selected, closely monitored patients lithium can be a helpful adjunct. Starting dosages of both drugs were moderate to high. Another disturbing aspect of the recorded cases was the continued use of these drugs for varying periods up to four days after serious if not critical physical and mental deterioration was recognized. Cohen and Cohen considered the possibility of encephalitic syndromes to be unlikely because there were no clinical signs of meningeal irritation and no evidence of inflammation or viral or other infection on laboratory tests. Nevertheless, the most sophisticated viral diagnostic studies do not always yield positive findings in documented cases of encephalitis, in part due to limitations of present methods (9). The occurrence of fever and abnormal enzyme and abnormal blood sugar tests in all patients, the singular outbreak of four cases at the same hospital within a given period of time, and the absence of similar problems before or since, despite continued use of the haloperidol-lithium combination at that institution, suggest a possible infectious etiology.

Human and animal studies are currently under way to investigate these issues further. However, until objective data are available to indicate otherwise, continued use of this drug combination can be carried out safely, effectively, and with FDA approval. The decision to use the combination, as with either drug alone, should be guided by assessments of physical and psychiatric diagnosis and attention to any underlying metabolic or other abnormalities. Serum lithium monitoring is required, but it is by no means a substitute for close clinical observation and careful dosage adjustments when necessary. Finally, although there should be no reluctance to use the combination where applicable, there should also be no hesitation to temporarily withhold or discontinue both drugs at once if significant deleterious effects develop.

We thank Dr. Brust for commenting on our study and the Editor for providing an opportunity to disseminate this information and expand discussion of the Cohen and Cohen report.

The article "Agitated Psychotic Depression Associated with Severe Hypomanic Episodes: A Rare Syndrome," by Jonathan M. Himmelhoch, M.D., Patricia Coble, R.N., David J. Kupfer, M.D., and Jane Ingenito, R.N., M.S.N. (July 1976 issue) should have stated that the work reported was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grant MH-24652 from the National Institute of Mental Health.

BOOK REVIEWS

The Sanctity of Social Life: Physicians' Treatment of Critically Ill Patients, *by Diana Crane. New York, N.Y., Russell Sage Foundation (Basic Books, distributor), 1975, 277 pp., $13.50.*

This book comes at an opportune time: the ethical aspects of medical practice are under close scrutiny. It is based on responses to over 3,000 questionnaires completed by physicians as well as a variety of extensive interviews with members of various medical specialties. The emphasis of the questionnaires and interviews was directed toward learning what physicians do rather than what they believe concerning the patient whose outlook is hopeless.

The author found that active treatment was most likely to be emphasized when the individual was capable of interacting with others in a meaningful way and least likely when the patient's condition was an entirely passive one. Positive euthanasia was a widespread practice for patients who had no capacity to live with any enjoyment. As yet, however, even negative euthanasia is not approved. As a result (because of technical devices that maintain life even in the absence of consciousness), many persons are kept alive at enormous expense to their families, to institutions, and to society.

This book is not easy to read, but it contains so much that is pertinent to present-day quandaries in medicine that the effort expended is well rewarded.

DANA L. FARNSWORTH, M.D.
Boston, Mass.

The Politics of Drugs: Marijuana to Mainlining, *by Richard C. Schroeder. Washington, D.C., Congressional Quarterly, 1975, 205 pp., no price listed (paper).*

The author's main theme in this book is an attempt to review the many contradictions in American attitudes toward drug use, although he views the United States as having a drug-oriented culture. Largely due to political foibles, he states, the Washington-based power merchants who dominate the drug field have spread "nonsense, misinformation, false propaganda, and panic" about drug use and abuse. Mr. Schroeder traces the changing strategies in law enforcement from 1914, when the Harrison Narcotic Act was passed, to the present. He reviews the many legislative acts and federal agencies that have been created and phased out.

In his opening chapter Mr. Schroeder reviews the myths and facts about drug abuse. In four following chapters he focuses on the many questions regarding marijuana (e.g., Is it harmful? Should it be legalized?). He then discusses such aspects of narcotics as classification, pharmacology, treatment, and international drug traffic.

The last two chapters emphasize the failure of law enforcement in the drug field in spite of the billions of dollars expended. He states, "The high cost of abuse [of drugs] is directly related to the policy of social prohibition [in this country] for more than half a century. . . . Drug use cannot be stamped out by legislative fiat." He warns that the goal of achieving a balanced view regarding drug use and abuse is very difficult to achieve in the face of changing political programs, the flaws in public information and education, distortions set forth by the mass media, and the enormous drug abuse "establishment," i.e., pharmaceutical companies, their lobbies in Washington, D.C., and the government drug abuse bureaucracy.

The sources for the author's material come largely from his review of reports of national commissions, congressional acts, national magazine research accounts, and reports of the privately based Drug Abuse Council, a group he has worked with extensively. The largest number—17—of his suggestions for readings are Drug Abuse Council publications. Next—15—are government documents and publications. There are only a few references to medical articles.

This book is well written, more in the style of the science writer who has amassed a great deal of data about subject matter that is still controversial. Mr. Schroeder's style affords him an opportunity to express opinions and value judgments. His view of drug abuse and addiction is more in tune with a sociological model than the medical model.

MANUEL M. PEARSON, M.D.
Philadelphia, Pa.

Identity Group Psychotherapy with Adolescents, *by Arnold W. Rachman, Ph.D. Springfield, Ill., Charles C Thomas, 1975, 299 pp., $16.75.*

This book's theoretical framework is drawn primarily from Erik Erikson's eight stages of man (1), chiefly from the fifth stage, the identity-versus-role-diffusion phase of adolescent development. The fifth stage task of psychological identification is translated from developmental theory into a practical practice labeled "group identity psychotherapy" that is faithful to Erikson's theory. The goal of this therapy is to help adolescents successfully achieve resolution of an existing identity crisis; the specific psychotherapy, described in detail, is prescribed for adolescents who, for one reason or another, are failing to achieve adequate resolution of that evolutionary stage in personality development.

The book reads easily. It is developed clearly, step by step, from theory into practice. It remains faithful to its heritage—Erikson's ego psychology by way of Freud's psychoanalytic theory.

It would be easy to go along with many assumptions in the text because of the manner of presentation of the material. For example, it is implied that the core of all adolescent psychological problems focuses on an ego developmental abnormality (identification crisis) and that nearly all adolescents can best be treated by the group therapy process discussed in the text. Dr. Rachman concentrates so much on his commitment to the recommended theory and derived therapy

that he might rightly be criticized as opinionated rather than scientific. However, I have no fundamental criticism of this aspect of the book because the scientific validity of all of the various psychotherapies continues to be a matter of divergent opinion; this book simply accepts one of them—a respected and valued one at that.

There are a number of typographical and editing errors in this book, the most glaring of which is a major misprint in the listing of the chapters. The book is well referenced, and there is a useful subject index.

I highly recommend the book to everyone treating adolescents rather than just theorizing about them. It takes a notable theory and translates it into a sensitive, practical, detailed, and responsible psychotherapy for adolescents. It serves as an informative and compact review of a broader concept for those who may be too narrowly or too intensively involved in individual or group adolescent psychotherapy. I would also recommend this book as an excellent text for use as a teaching and learning guide for those thinking of developing skill in group psychotherapy with emotionally troubled adolescents.

Understanding Human Behavior for Effective Police Work, *by Harold E. Russell and Allan Beigel. New York, N.Y., Basic Books, 1976, 293 pp., $13.95.*

This textbook is designed to assist the police in understanding behavior as they work in the field. When one considers the emphasis on professional training for police officers in the United States and the input of mental health professionals into this training, it is easy to see the interest this book has for readers of this journal. In addition to writing a textbook for the police, the authors have also made available a source book for mental health professionals who are teaching the police.

The professional role of the police officer has changed significantly as society has undergone social, legal, and moral change. This book highlights the professionalism of the police and supplies them with an opportunity to improve the level of their work.

After a discussion of aspects of the changing role of the police officer, the book is divided into the three following parts: The Origins and Complexities of Human Behavior, Understanding Mental Illness, and Assessing and Managing Abnormal Behavior in the Field.

The section on human behavior contains an excellent chapter on normal growth and development that has a decidedly psychodynamic orientation as well as many references to Freudian theory. The explanations of defense mechanisms and a chapter on abnormal behavior are very well done and could be used to instruct such groups as teachers, nonpsychiatrist physicians, and the clergy.

In the section on understanding mental illness, the brief but elegant chapters titled "Classification of Abnormal Behavior," "Personality Disorders," "The Neuroses," and "The Psychoses" include relevant case examples. The case examples throughout the text attempt to describe clinical syndromes as seen through the police officer's eyes.

A most valuable part of this book is the section dealing with the management of abnormal behavior. Not only are various kinds of behavior described (e.g., psychopathic behavior, deviant sexual behavior, and delinquent behavior), but the reader is given a series of "helpful hints" for the law enforcement officer in relationship to each behavior. These are in no way cookbook rules; rather, they provide an opportunity to exercise judgment based on an understanding of what has been discussed in the section. From the point of view of the mental health professional, the chapters on violent behavior and suicidal behavior are as well written as any I have seen. There are also excellent chapters on aspects of riots and disaster. The authors present a code of conduct for police officers during civil disturbances and riots.

The last chapter contains a discussion of such legal issues as criminal responsibility, competency, and confidentiality. This discussion is of use to a great variety of professional people.

This is an extremely well written book containing excellent case examples; it is enjoyable to read as well as quite sophisticated. I strongly recommend this book not only for professional police officers but also for professionals who are teaching police officers, participating in the selection of police officers, or performing preventive psychiatry in a variety of settings.

Armed Robbery: Offenders and Their Victims, *by John M. Macdonald, M.D. Springfield, Ill., Charles C Thomas, 1975, 438 pp., $18.50.*

Crime is a human behavior, and as such it ought to interest psychiatrists more than it does. Understandably, there is revulsion in dealing with the subject, and our profession generally tends to view criminals as belonging in the forensic realm, as people who ought to be dealt with by the police. In this respect, the series of volumes by John Macdonald over the years on the criminal, murder, rape, indecent exposure, and now armed robbery constitute valuable texts for clinicians who wish to become more familiar with these subjects. Macdonald is a psychiatrist with a wealth of clinical and forensic experience. In one of his earlier volumes (1) he studied a large group of homicidal psychiatric patients; in this volume he analyzes 1,000 armed robberies with the help of members of a police department. He finds that 1 in 250 ended in homicide.

The volume contains anecdotal accounts of robberies, including bank robberies and skyjackings, plus some attempts to understand the history of robbery, accounts of famous robbers, and discussions of society's attitudes toward and identification with the robber and the effects of punishment (this is handled superficially in the book). Psychological understanding of the armed robber, his or her motives, the acts that get him or her caught, and some psychodynamics will interest the reader. There is a great deal of descriptive material, and there are many anecdotes, some of which are quite frightening.

The book is long but generally well referenced. One can use it as a reference text or can read it lightly in an evening to understand how the police act, what the criminal is like, and where armed robbery occurs and to become acquainted with a class of offenders unfortunately prevalent in our society.

I recommend this book, although Macdonald's earlier book titled *Psychiatry and the Criminal* (1) fulfills something of the same goal and would more generally acquaint the clinician with the problems of crime. *Armed Robbery* deals more in depth with one type of crime, criminal, and victim.

JOHN R. LION, M.D.
Baltimore, Md.

The Patient and the Therapist: New Light on the Psychotherapist, *by Arthur Burton. Sacramento, Calif., Hamilton Psyche Press, 1975, 168 pp., $8.95.*

In this collection of 13 essays, 8 of which have been published before, Burton's intent is to focus upon "the humanness and genuineness of the healer as opposed to his screen, reflective and cognitive purpose." That both affect and intellect are central to the therapist's armamentarium is given suitable acknowledgment, but it is the affective and human side that is the concern in this book.

Burton refers to the profusion of therapies, the plethora of hypotheses, and the variegated therapeutic styles that all lay claim to healing. Encounter groups, primal scream therapy, and transactional analysis, as well as a variety of apparently subsiding counterculture experiences (including the drug scene), compete with and often enough deride psychoanalytic psychotherapy and psychoanalysis. To some extent the style of this book mirrors the voices and advocates that are heard from all sides. The style does not displease; indeed, it reflects broad experience, openness, and inquisitiveness. However, in an apparent wish to touch a great many bases the author darts about in a somewhat breathless fashion.

The book contains useful insights, as when Burton refers to wild therapists and wild analysts who have a tremendous unconscious need either to flee from therapeutic intimacy, to participate even more deeply in it, or to innovate as an end in itself. On the other hand, from a previous study of therapists Burton posits that the psychological background of a therapist is one in which he idealizes his father and often depreciates his mother. This seems based on very thin ice indeed. Further, Burton reports that few of the healers he studied had kind words to say about their training analyses. All felt with great certitude that their true growth came from and with their patients. Let me be recorded in a different mode: growth in terms of range, experience, and clinical acumen certainly comes from diligent work with patients, but I will number myself among those whose greatest growth came from my training analysis.

There are essays on the lives and therapeutic styles of therapists, sources of therapist satisfaction, and the therapist as a patient. The chapter on the presentation of the therapeutic face is a particularly useful contribution because it calls to our attention the therapeutic face as nonverbal communication and transference screen. In addition, the therapeutic face has an array of reactions that are read, assumed, or acted out. In the chapter on hope and psychotherapy Burton calls for an extensive discussion that can be touched only in the sense that the place of hope in psychotherapy might have been linked with the place of fantasy, expectation, and denial.

In the final chapter, which concerns the therapy of the nondiseased person, Burton describes an experiment in which he treated individuals who neither needed nor wanted psychotherapy. It would have been helpful if the concepts of character, character traits, and character disorder had been included in the book, but one suggestion cannot escape notice. Burton states that therapists fear their patients' impulses, their acting out, and even their creativity. If by acting out Burton means the transformation into behaviors of fantasies, impulses, and conflicts that are in the process of being worked through in the therapy, the therapist who identifies and deals with acting out for what it is does not have such difficulty.

Burton presents us with an eclectic view of an aspect of the current psychotherapeutic scene in the United States. The problem is to distinguish eclecticism from bedlam.

JACOB SWARTZ, M.D.
Boston, Mass.

Hypnotics: Methods of Development and Evaluation. Proceedings of the Brook Lodge Conference on Hypnotics, *edited by Fred Kagan, Theresa Harwood, Karl Rickels, Allan D. Rudzik, and Heinz Sorer. New York, N.Y., Spectrum Publications (Halsted Press, John Wiley & Sons, distributor), 1975, 416 pp., $30.00.*

In his introduction Dr. Kagan asserts that previous symposia on sleep have devoted themselves to the phenomenology of sleep and ignored the pragmatic aspects of evaluating and developing drugs to treat sleep problems. Herein lies the value of this book. After first presenting an overview of sleep disorders and their treatment, the various contributors then address themselves to methods for the clinical evaluation of hypnotics. The remainder of the volume is divided into two other major sections. One concentrates on evaluation of addiction liability, a topic of great practical importance in determining suitability of hypnotics for an individual patient. The second and final section contains several chapters on the metabolism and adverse effects of hypnotics.

No up-to-date consideration of the applicability of psychotropic drugs is complete without a review of the current knowledge derived from studies of drug metabolism, including pharmacokinetics, rate of drug turnover, individual variation, and the regulatory role of microsomal enzymes in the liver. Leibman and Alvares in separate chapters discuss the more basic aspects of these subjects, and Azarnoff addresses the clinical implications of changes in drug metabolism.

This volume is compiled from the proceedings of the Brook Lodge Conference on Hypnotics held in Augusta, Mich., in July 1974. Many symposia suffer from a time lag. As a result, information in print may summarize findings two or three years old. The present editors have avoided that pitfall by rushing their proceedings into print in a relatively rapid time. As a result, the findings are still fresh and current. Another major weakness of most printed symposia are the discussions that follow formal presentations. The discussion period is often filled with somewhat repetitive and occasionally irrelevant questions that the speaker is often hard put to answer. This does not appear to be the case in *Hypnotics*. Either such questions were not asked or, more likely, they were carefully edited out. Many facts are brought up in the discussions; this enhances the timeliness of the book be-

cause they recount even more recent data than is discussed in the formal paper or contain the findings of coworkers who were not on the formal program. Another feature of this book that should be very helpful is the references, which apply not only to the formal presentations but to the material covered during the discussions as well.

The least valuable part of the book is the section on evaluation of addiction liability. Perhaps because of its roundtable format and the large number of formal participants (six), as well as numerous comments from the audience, it was difficult to come away with any clear-cut pattern of conclusions that would be of clinical value in determining addiction liability. Too often, just as one participant was beginning to explore material in depth, the subject was changed either by another participant or an audience member. Perhaps this cannot be avoided at round tables. Unfortunately, they frequently do not "read" well; this chapter is no exception to this observation.

In spite of this minor criticism, the volume is a worthwhile investment for anyone seriously interested in the subject of hypnotics.

SIDNEY MALITZ, M.D.
New York, N.Y.

Perinatal Addiction, *edited by Raymond D. Harbison. New York, N.Y., Spectrum Publications (Halsted Press, John Wiley & Sons, distributor), 1975, 384 pp., no price listed.*

The papers in this informative book were presented at a 1974 conference cosponsored by the National Institute on Drug Abuse (NIDA) and Vanderbilt University, Nashville, Tenn.

Psychiatrists can learn a great deal from this book about the impact of maternal drug and alcohol use on the developing fetus. Several papers provide excellent descriptions of neonatal withdrawal and its management. This information will facilitate communication between psychiatrists and pediatricians; however, there is little help here for the psychiatrist called in as a consultant.

An overall emphasis on developmental pharmacology is reflected in the book's title. The terms "addict" and "addiction" occur in the titles of 6 of the 26 papers. The authors, all of whom are pediatricians or pharmacologists, use these terms to refer only to physiological, not to psychological, dependence in affected infants. Neutral descriptive phrases such as "neonatal abstinence syndrome" are used in some instances in the book. These neutral phrases may be more awkward, but they are preferable to such negative labels as "addict" when applied to newborn children.

The most useful paper, from a psychiatric point of view, is Coppolillo's, titled "Drug Impediments to Mothering Behavior." He describes genetic, characterological, and environmental factors that impair parenting skills. Coppolillo advocates early and repeated maternal contact with each newborn baby but does not accompany this excellent advice with technical suggestions. Psychiatrists attempting to help facilitate parent-child bonding must find their own course between the Scylla of medical treatment, which may isolate or sedate the infant, and the Charybdis of maternal avoidance stemming from anxiety, guilt, and low self-esteem.

Important issues concerning the treatment and prevention of alcohol and drug dependence are raised by this book. The disturbing sequelae surrounding pregnancy and delivery are well described. Obviously, a great deal remains to be done in developing effective psychiatric treatment of affected mothers and their families.

Although written primarily by and for pediatricians and pharmacologists, *Perinatal Addiction* serves as a challenge to psychiatrists to become involved in finding ways of managing and preventing this complex problem.

JOHN N. CHAPPEL, M.D.
Reno, Nev.

Bereavement: Its Psychosocial Aspects, *edited by Bernard Schoenberg, Irwin Gerber, Alfred Wiener, Austin H. Kutscher, David Peretz, and Arthur C. Carr. New York, N.Y., Columbia University Press, 1975, 367 pp., $15.00.*

This volume reflects the continuing energetic efforts of the Foundation of Thanatology. This organization produces annually a collection of papers oriented toward a particular aspect of the theme of dying, death, or bereavement. This book is identical in format to the previous ones in this series. Included are 31 chapters of varying length, style, lucidity, and significance. The chapters are distributed among five parts: Fundamental Concepts, The Bereavement Process, The Bereaved Family, The Health Professional, and Therapeutic Intervention.

Several of the chapter authors are well known in the field, e.g., Clayton, Krant, Parkes, and Silverman. Despite this fact, the book lends itself to criticism in that many of the topics relating to bereavement have been covered in previous books sponsored by the Foundation of Thanatology (1, 2).

Nevertheless, some of the chapters appealed to me. "The Process and Phenomenology of Bereavement" by Wiener and associates is a prospective study of families. An important finding of these authors is that the number of deaths, major hospitalizations, and psychiatric decompensations did not increase following bereavement. This finding is in contrast to the prevalent assumption that the opposite is true. Wiener and associates did note an increase in the number of doctor visits, use of medications, and number of subjective symptoms, however. In "Studies in Grief," Schwab and associates state that 50% of the bereaved population they studied displayed intense grief reactions more than one year after the loss.

Lerner's article, "Changes in Attitudes Toward Death: The Widow in Great Britain in the Early Twentieth Century," is interesting from a historical point of view. Parkes's chapter, "Unexpected and Untimely Bereavement: A Statistical Study of Young Boston Widows and Widowers," should encourage the reader in the direction of his book, which considers the topic in depth (3).

Rosenblatt's chapter, "Uses of Ethnography in Understanding Grief and Mourning," provides a useful background perspective for workers in the field. He cautions professionals to be aware of the "possibility that self-fulfilling prophecy may lead to the adoption of suboptimal practices." In a similar vein, in "The Health Professional" Krant discusses in an attractive and sobering style the difficulties encountered by the researcher, not only in terms of the hypotheses but in terms of carrying out the practicalities of the project.

Showalter's overview, "Parent Death and Child Bereavement," and Schoenberg and associates' "Advice of the Bereaved for the Bereaved" present welcome specific approaches to the problem of support for the grief stricken of all ages.

I would suggest that grief and its mental expression, mourning, are responses to any actual or threatened separation, not only to the loss of a loved one. One cannot "help" those who mourn in advance of the loss or through psychological clichés. Kutscher and Kutscher state in their preface, "Care must be taken lest the humanitarian dimensions of psychosocial concepts be diminished by intellectual detachment." I could not agree more (4).

Modern Perspectives in the Psychiatry of Old Age, *edited by John G. Howells, M.D., D.P.M., New York, N.Y., Brunner/Mazel, 1975, 604 pp., $20.00.*

This book provides a surfeit of riches for the clinician, the teacher, and any serious student of aging. It often goes beyond the limits of its title to provide information, data, and views of value to fields other than psychiatry, such as psychology, sociology, and ethics. As a compendium it has some flaws, but these are a small price to pay for the breadth and variety of views expressed.

Of particular importance are the several chapters in which the personal styles and viewpoints of several very experienced writer-clinicians are expressed. As an example, the general subject of treatment and the attitudes of the treater are dealt with in chapters on psychopathology, psychoneurosis, associated organic status, and death and dying, to name only the outstanding examples. Each of these deals well with its own subject, but the astute reader can learn much from the differing viewpoints and styles.

Of special interest to readers in the United States should be several chapters written by non-Americans. These include the chapter on epidemiology by N. Juel-Nielsen of Denmark, the one on concomitant physical states by Anderson and Davidson of Scotland, the one on nosology by Bergmann of England, the one on psychosomatic states by Stenbäch of Finland, and the one on confusional states by Kral of Canada.

A truly outstanding chapter is the one by Professor Sternberg of Russia. It was a joy to note the precision in this author's use of English, especially in the preamble, and the equally precise logic in the initiation of the central idea. The construction and progression of the logic of the chapter is an excellent example of clarity in medical writing. The device of nosology is used as a vehicle for presenting some views about diagnosis and treatment that, but for the deftness of their presentation, might arouse resistance. Also clearly apparent is the strength of the opinions or views expressed; if one were so inclined one could read into the style a hint of rigidity and work by committee. The basic concept presented—that continuity of the aging process should dictate continuity of specialized services to meet needs regardless of chronological age—is being advanced elsewhere (1, 2).

The psychology of aging is dealt with in two chapters, one by American and one by British authors, thus giving the reader a chance to make some interesting comparisons. I found Fozard and Thomas' article informative and lucidly written even though it presented complex research findings. In my view this chapter alone justifies reading the book; it has the most current data of any of the chapters and has a most complete bibliography. Another subject these authors clearly describe in some depth is the differential effects of age on the various abilities of intelligence, attitudes, and behavior. Knowledge of these differences gives the clinician a scientific basis for sound treatment plans and a hopeful attitude toward the elderly. This is especially true when one realizes that some intellectual capacities do not reach their peak performance until the individual's fifth and sixth decades.

Any book by many authors must have some unevenness or shortcomings, only a very few of which are substantial in this book. The initial chapter is disappointing because it does not present newer knowledge about the structure of chromosomes and its relationship to differential aging or to cellular or protoplasmic aging.

Also absent from the book is reference to some of the most recent advances in diagnostic aids, such as the neurological index of mental impairment (NIMI) (3, 4). This test attempts, usually successfully, to identify and quantify very early or incipient intellectual deficit when it is most difficult to identify but when it would be most helpful for subsequent management.

Also missing is reference to the electronically magnified image (EMI) (5–8), a noninvasive, more reliable X-ray means of visualizing intracranial pathology. I would also like to have seen the inclusion of newer workers such as Butler and Pattison and established writers such as Busse, Schneideman, and Simon, but a line must be drawn somewhere.

A chapter on alcohol and other drug abuse by the elderly would also have been of great usefulness, as would a special emphasis on the correction of sensory deficits of aging, especially the most pressing problem of impaired hearing. The impact on emotional health of several social factors such as housing, income level, transportation, and de facto discrimination is of increasingly recognized importance but is not dealt with in this work.

I read the book as a clinician in private practice, as a teacher, and as a health administrator and found it useful in each area. It should be widely used in medical schools and graduate courses in several fields. Fortunately, it is nontechnical and readable enough to be of value to the well-informed layman, and mental health workers will find it an easy book to browse through and to read. A major asset is that nearly every chapter has extensive references that will make the book especially valuable to researchers. Both the author index and the general index were more than adequate. In summary, this book is a period piece deserving a place on the bookshelf of anyone with a serious interest in teaching or learning about aging.

Program Evaluation: Alcohol, Drug Abuse, and Mental Health Services, *edited by Jack Zusman and Cecil R. Wurster. Lexington, Mass., Lexington Books (D.C. Heath and Co.), 1975, 272 pp., $14.00.*

This pioneering book explores the new and rapidly evolving art and science of evaluating human service programs. Industry monitors its productivity by cost-effectiveness studies. Health delivery systems are now being asked to do the same. The people who pay for these services either directly or indirectly, through taxes or insurance premiums, have a right to know how their money is being spent. This book deals with the problems encountered as well as the progress being made in trying to evaluate treatment results in the intangible fields of alcoholism, drug addiction, and mental illness.

The need for such analyses is apparent. If our increasingly limited resources are to be used to their best advantage, we have to know which programs really help and which do not. The technical difficulty of obtaining a valid appraisal is compounded by the natural reluctance of most practitioners or agencies to risk an adverse survey. Negative self-evaluations are hushed up as potentially self-destructive. Outside surveys are costly, interfere with the primary work of the facility, sacrifice confidentiality, and can be damaging if the results are interpreted incorrectly or released inappropriately.

The use of evaluations as a political tool to support or destroy programs is an ever present danger. Distorted interpretations of accurate raw data can be used by the government to validate projects that are ineffective and to lull the public into believing that "something is being done" to "solve" community problems. Clinically effective services that are too costly (e.g., state hospitals) can be dismantled under the guise of an adverse systems analysis.

Appraisals of programs are usually made after a project has been started and committed to a course of action. Evaluations at this stage can be of assistance if they help to improve performance, promote a wiser allocation of resources, and define realistic goals. Whenever possible, the emphasis should be on education rather than regulation.

Although this book does not discuss those surveys with which most of us are familiar, such as those of the Joint Commission on the Accreditation of Hospitals, Professional Standards Review Organizations and other peer-review groups, utilization review groups, and licensing boards, it is pertinent to these endeavors. Our own medical journals have always published excellent studies of treatment outcome. Few articles, however, examine the cost effectiveness of our psychiatric treatment modalities. Perhaps it is time to research this aspect of our practice as well.

FREDERICK LEMERE, M.D.
Seattle, Wash.

The Practice of Mental Health Consultation, *edited by Fortune V. Mannino, Beryce W. MacLennan, and Milton F. Shore. New York, N.Y., Gardner Press (Halsted Press, John Wiley & Sons, distributor), 1975, 241 pp., $12.95.*

This volume is a collection of articles by 14 contributors based on the authors' experiences in Prince Georges County, Md. It is the goal of the editors to make available the insight gained in these experiences in a variety of circumstances. The editors summarize the contents of the book very well in their preface:

> The book covers several areas of consultation. The first chapter deals with the definition and scope of consultation from the perspective of a community mental health center. The second chapter covers the research literature on the effectiveness of consultation. Chapters 3 through 7 are descriptive reports of consultation programs in a variety of community settings, including schools, day care centers, the police, and the new youth-oriented programs. Chapter 8 describes experiences in the training of mental health consultants. Chapter 9 offers a number of vignettes which illustrate some of the key issues and problems in the planning, implementation and practice of mental health consultation. Finally, the appendix offers a complete revision of the report entitled, Consultation in Mental Health and Related Fields: A Reference Guide. Originally published in 1969, the Reference Guide is now both outdated and out of print. The revision updates the Guide through 1973.

This book should serve as a valuable reference for mental health practitioners and an even more valuable text for college courses. The latter purpose warrants exploration by educators who may have overlooked mental health consultation as a viable occupational goal for their students. The practitioner will find descriptions of various settings in which consultation takes place; the details of this process, including problems inherent in mental health consultation, are especially useful.

The major weakness of the book is the failure to provide more detail regarding the problem of funding consultation services. Although the editors state that the problem of funding is a reality, they fail to provide information that would be helpful to administrators regarding cost analysis and contract negotiations for consultation programs.

The reference guide is extensive and comprehensive and should prove extremely valuable and helpful to anyone interested in mental health consultation.

NORMAN L. LOUX, M.D.
Sellersville, Pa.

This Month's Reviewers

DANA L. FARNSWORTH, M.D., is Henry K. Oliver Professor of Hygiene, Emeritus, Harvard University, Cambridge, Mass.

MANUEL M. PEARSON, M.D., is Professor of Clinical Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, Pa.

RICHARD E. DAVIS, M.D., is Vice-President for Health Affairs and Dean, School of Medicine, University of North Dakota, Grand Forks, N.D.

ALAN M. ELKINS, M.D., is Chief of Psychiatry, Maine Medical Center, Portland, Me.

JOHN R. LION, M.D., is Associate Professor and Director, Clinical Research Program for Violent Behavior, Department of Psychiatry, University of Maryland School of Medicine, Baltimore, Md.

JACOB SWARTZ, M.D., is Professor of Psychiatry, Boston University School of Medicine, and Training and Supervising Analyst, Boston Psychoanalytic Society and Institute, Boston, Mass.

SIDNEY MALITZ, M.D., is Professor and Acting Chairman, Department of Psychiatry, College of Physicians and Surgeons of Columbia University, and Acting Director, New York State Psychiatric Institute, New York, N.Y.

JOHN N. CHAPPEL, M.D., is Professor of Psychiatry, University of Nevada, Reno, Nev.

NATHAN SCHNAPER, M.D., is Professor of Psychiatry, University of Maryland School of Medicine, Baltimore, Md.

J.M. STUBBLEBINE, M.D., is Associate Clinical Professor of Psychiatry, University of California, San Francisco, School of Medicine, San Francisco, Calif.; he is also in private practice in Greenbrae, Calif.

FREDERICK LEMERE, M.D., is Clinical Professor of Psychiatry, University of Washington School of Medicine, Seattle, Wash.

NORMAN L. LOUX, M.D., is Medical Director, Penn Foundation for Mental Health, Sellersville, Pa.

Books Received

This listing acknowledges the receipt of recent books. Books of particular interest to the readers of this journal will be reviewed as space permits, and copies of the reviews will be sent to the publishers. Books cannot be returned to the publisher.

The Meditation Handbook, *by Tom Alibrandi. Chatsworth, Calif., Major Books, 1976, 148 pp., $1.25 (paper).*

Comprehensive Psychiatric Care, *edited by AA Baker, C.B.E., M.D. Oxford, England, Blackwell Scientific Publications (Philadelphia, Pa., J.B. Lippincott Co., distributor), 1976, 287 pp., $21.50.*

Basic Child Psychiatry, 2nd ed., *by Philip Barker, M.B., D.P.M., D.C.H. Baltimore, Md., University Park Press, 1976, 268 pp., $14.50*

The Reality Therapy Reader: A Survey of the Work of William Glasser, M.D., *edited by Alexander Bassin, Ph.D., Thomas Edward Bratter, Ed.D., and Richard L. Rachin, M.P.A. New York, N.Y., Harper & Row, 1976, 673 pp., $15.00.*

Save Your Marriage, *by Barry Robert Berkey, M.D. Chicago, Ill., Nelson-Hall, 1976, 290 pp., $9.95.*

Psychology of Deafness for Rehabilitation Counselors, *edited by Brian Bolton, Ph.D. Baltimore, Md., University Park Press, 1976, 149 pp., $14.50.*

Principles of Learning and Memory, *by Robert G. Crowder. Hillsdale, N.J., Lawrence Erlbaum Associates (New York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1976, 505 pp., no price listed.*

The Behavioral Management of Anxiety, Depression and Pain, *edited by Park O. Davidson, Ph.D. New York, N.Y., Brunner/Mazel, 1976, 188 pp., $13.50.*

Mechanisms in Transmission of Signals for Conscious Behaviour, *edited by T. Desiraju. Amsterdam, The Netherlands, Elsevier Scientific Publishing Co. (New York, N.Y., American Elsevier Publishing Co., distributor), 1976, 366 pp., $46.25.*

The Hungry Fly: A Physiological Study of the Behavior Associated with Feeding. A Commonwealth Fund Book, *by V.G. Dethier. Cambridge, Mass., Harvard University Press, 1976, 477 pp., $30.00.*

Emotional Problems of Living: Avoiding the Neurotic Pattern, 3rd ed., *by O. Spurgeon English, M.D., and Gerald H.J. Pearson, M.D. New York, N.Y., W.W. Norton & Co., 1976, 610 pp., $5.95 (paper).*

Alternative Education: A Source Book for Parents, Teachers, Students, and Administrators, *edited by Mario D. Fantini. Garden City, N.Y., Anchor Press/Doubleday, 1976, 488 pp., $4.50 (paper).*

Results of 11 controlled studies[1] evaluated by the Brief Psychiatric Rating Scale to determine the efficacy of LOXITANE® Loxapine Succinate by comparing it with trifluoperazine and chlorpromazine. They do not imply a claim of differential effectiveness or superiority. However, certain trends, not statistically significant, suggest superiority. These require further tests for confirmation.

From the record:

LOXITANE has favorable trends

In 31 dose-range, long-term and controlled efficacy studies involving 469 acute and chronic schizophrenic patients...

Certain favorable trends were exhibited in the LOXITANE side effects profile; these require further tests and broader clinical experience for confirmation.

exhibited certain in side effects profile

While cardiac arrest, blood dyscrasias and renal toxicity have been reported with other antipsychotic agents, they have not been seen with LOXITANE. Hepatotoxicity manifested by jaundice or biliary stasis has not been observed. Transient liver enzyme changes, however, have been reported, but it has not been determined whether they are related to LOXITANE administration.

Although a few cases of changes in ECG have been reported, a causal relationship between this reaction and LOXITANE has not been established. Clinical experience with LOXITANE has not demonstrated ocular toxicity, however, the possibility of its occurrence cannot be ruled out at this time. Of the various endocrine abnormalities, only galactorrhea has been noted with LOXITANE, and only in rare instances.

Manifestations of adverse effects on the central nervous system other than extrapyramidal symptoms have been encountered infrequently, and drowsiness, when it occurs, is usually mild and subsides with continued therapy. Skin rashes of uncertain etiology have been observed in a few patients during the hot summer months; therefore the possibility of phototoxicity and/or photosensitivity cannot be excluded. Like certain other antipsychotic agents, LOXITANE lowers the convulsive threshold and should be used with extreme caution in patients with a history of convulsive disorders.

In general, LOXITANE presents a profile of extrapyramidal side effects similar to that of other agents used in the treatment of schizophrenia.

Cardiovascular effects such as hypotension, hypertension, light-headedness and syncope have been reported. Anticholinergic effects seen with LOXITANE include dry mouth, nasal congestion, constipation and blurred vision.

See LOXITANE prescribing information on next page for contraindications, warnings and precautions and for more detailed information concerning side effects.

A range of dosage strengths to suit the patient's individual needs

Supplied

Capsules

10 mg Green and Yellow

25 mg Green Two Tone

50 mg Green and Blue

Recommended Daily Dosage

Initial Dosage	MILD 10 mg b.i.d.	MODERATE 10 mg t.i.d. or q.i.d.	SEVERE 25 mg b.i.d.
First 7 to 10 Days	Increase dosage until psychotic symptoms are controlled. Dosage should not exceed 250 mg/day. Usual dosage during titration: 50 to 150 mg/day.		
Maintenance Dosage	Adjust to lowest effective level. Usual maintenance dosage: 60 to 100 mg/day. Many patients are controlled with dosages as low as 20 to 60 mg/day.

Because efficacy and side effects are a single consideration

FOR ORAL USE

PRODUCT INFORMATION

DESCRIPTION

LOXITANE *loxapine*, a dibenzoxazepine compound, represents a new subclass of tricyclic antipsychotic agent, chemically distinct from the thioxanthenes, butyrophenones, and phenothiazines. Chemically, it is 2 - chloro - 11 - (4 - methyl - 1 - piperazinyl) dibenz [b,f] [1,4] oxazepine. It is present in capsules as the succinate salt. Each 1.36 mg of loxapine succinate is equivalent to 1 mg of loxapine.

ACTIONS

Pharmacologically, loxapine is a tranquilizer for which the exact mode of action has not been established. However, changes in the level of excitability of subcortical inhibitory areas have been observed in several animal species in association with such manifestations of tranquilization as calming effects and suppression of aggressive behavior.

In normal human volunteers, signs of sedation were seen within 20 to 30 minutes after administration, were most pronounced within 1½ to 3 hours, and lasted through 12 hours. Similar timing of primary pharmacologic effects was seen in animals.

Absorption of loxapine following oral or parenteral administration is virtually complete. The drug is removed rapidly from the plasma and distributed in tissues. Animal studies suggest an initial preferential distribution in lungs, brain, spleen, heart, and kidney. Loxapine is metabolized extensively and is excreted mainly in the first 24 hours. Metabolites are excreted in the urine in the form of conjugates and in the feces unconjugated.

INDICATIONS

LOXITANE *loxapine succinate* is indicated for the manifestations of schizophrenia.

CONTRAINDICATIONS

LOXITANE is contraindicated in comatose or severe drug-induced depressed states (alcohol, barbiturates, narcotics, etc.)

LOXITANE is contraindicated in individuals with known hypersensitivity to the drug.

WARNINGS

Usage in Pregnancy: Safe use of LOXITANE *loxapine succinate* during pregnancy or lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the benefits of treatment be weighed against the possible risks to mother and child. No embryotoxicity or teratology was observed in studies in rats, rabbits or dogs, although with the exception of one rabbit study, the highest dosage was only two times the maximum recommended human dose and in some studies they were below this dose. Perinatal studies have shown renal papillary abnormalities in offspring of rats treated from midpregnancy with doses of 0.6 and 1.8 mg/kg, doses which approximate the usual human dose but which are considerably below the maximum recommended human dose.

Usage in Children: Studies have not been performed in children; therefore this drug is not recommended for use in children below the age of 16.

LOXITANE, like other tranquilizers, may impair mental and/or physical abilities, especially during the first few days of therapy. Therefore, ambulatory patients

should be warned about activities requiring alertness (eg, operating vehicles or machinery), and about concomitant use of alcohol and other CNS depressants.

PRECAUTIONS

LOXITANE loxapine succinate should be used with extreme caution in patients with a history of convulsive disorders since it lowers the convulsive threshold. Seizures have been reported in epileptic patients receiving LOXITANE at antipsychotic dose levels, and may occur even with maintenance of routine anticonvulsant drug therapy.

Loxapine has an antiemetic effect in animals. Since this effect may also occur in man, loxapine may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

LOXITANE should be used with caution in patients with cardiovascular disease. Increased pulse rates have been reported in the majority of patients receiving antipsychotic doses; transient hypotension has been reported. In the presence of severe hypotension requiring vasopressor therapy, the preferred drugs may be norepinephrine or angiotensin. Usual doses of epinephrine may be ineffective because of inhibition of its vasopressor effect by loxapine.

The possibility of ocular toxicity from loxapine cannot be excluded at this time. Therefore, careful observation should be made for pigmentary retinopathy and lenticular pigmentation since these have been observed in some patients receiving certain other antipsychotic drugs for prolonged periods.

Because of possible anticholinergic action, the drug should be used cautiously in patients with glaucoma or a tendency to urinary retention, particularly with concomitant administration of anticholinergic-type antiparkinson medication.

ADVERSE REACTIONS

CNS Effects: Manifestations of adverse effects on the central nervous system, other than extrapyramidal effects, have been seen infrequently. Drowsiness, usually mild, may occur at the beginning of therapy or when dosage is increased.

It usually subsides with continued LOXITANE therapy. The incidence of sedation has been less than that of certain aliphatic phenothiazines and slightly more than the piperazine phenothiazines. Dizziness, faintness, staggering gait, muscle twitching, weakness, and confusional states have been reported.

Extrapyramidal Reactions—Neuromuscular (extrapyramidal) reactions during the administration of LOXITANE *loxapine succinate* have been reported frequently, often during the first few days of treatment. In most patients, these reactions involved Parkinson-like symptoms such as tremor, rigidity, excessive salivation, and masked facies. Akathisia (motor restlessness) also has been reported relatively frequently. These symptoms are usually not severe and can be controlled by reduction of LOXITANE dosage or by administration of antiparkinson drugs in usual dosage. Dystonic and dyskinetic reactions have occurred less frequently, but may be more severe. Dystonias include spasms of muscles of the neck and face, tongue protrusion, and oculogyric movement. Dyskinetic reaction has been described in the form of choreo-athetoid movements. These reactions sometimes require reduction or temporary withdrawal of LOXITANE dosage in addition to appropriate counteractive drugs.

Persistent Tardive Dyskinesia—As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movement of the tongue, face, mouth, or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinson agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Cardiovascular Effects: Tachycardia, hypotension, hypertension, light-headedness, and syncope have been reported.

A few cases of ECG changes similar to those seen with phenothiazines have been reported. It is not known whether these were related to loxapine administration.

Skin: Dermatitis, edema (puffiness of face), pruritus, and seborrhea have been reported with loxapine. The possibility of photosensitivity and/or phototoxicity occurring has not been excluded; skin rashes of uncertain etiology have been observed in a few patients during hot summer months.

Endocrine Effects: No endocrine abnormalities have been reported.

Anticholinergic Effects: Dry mouth, nasal congestion, constipation, and blurred vision have occurred; these are more likely to occur with concomitant use of antiparkinson agents.

Other Adverse Reactions: Nausea, vomiting, weight gain, weight loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, and polydipsia have been reported in some patients.

DOSAGE AND ADMINISTRATION

LOXITANE *loxapine succinate* is administered orally usually in divided doses two to four times a day. Daily dosage (in terms of base equivalents) should be adjusted to the individual patient's needs as assessed by the severity of symptoms and previous history of response to antipsychotic drugs. Initial dosage of 10 mg twice daily is recommended, although in severely disturbed patients initial dosage up to a total of 50 mg daily may be desirable. Dosage should then be increased fairly rapidly over the first seven to ten days until there is effective control of psychotic symptoms. The usual therapeutic and maintenance range is 60 mg to 100 mg daily. However, as with other antipsychotic drugs, some patients respond to lower dosage and others require higher dosage for optimal benefit. Daily dosage higher than 250 mg is not recommended. For maintenance therapy, dosage should be reduced to the lowest level compatible with symptom control; many patients have been maintained satisfactorily at dosages in the range of 20 mg to 60 mg daily.

HOW SUPPLIED

LOXITANE *loxapine succinate* is supplied in the following base equivalent strengths:

CAPSULES Hard Shell Printed "Lederle"

10 mg—Green and Yellow; Bottles of 100, 1000, and unit dose 10 x 10's—Product Number 5360

Tested by time and experience i

1962

"...a considerable decrease of hyperactivity...."[1]
Knobel, 1962

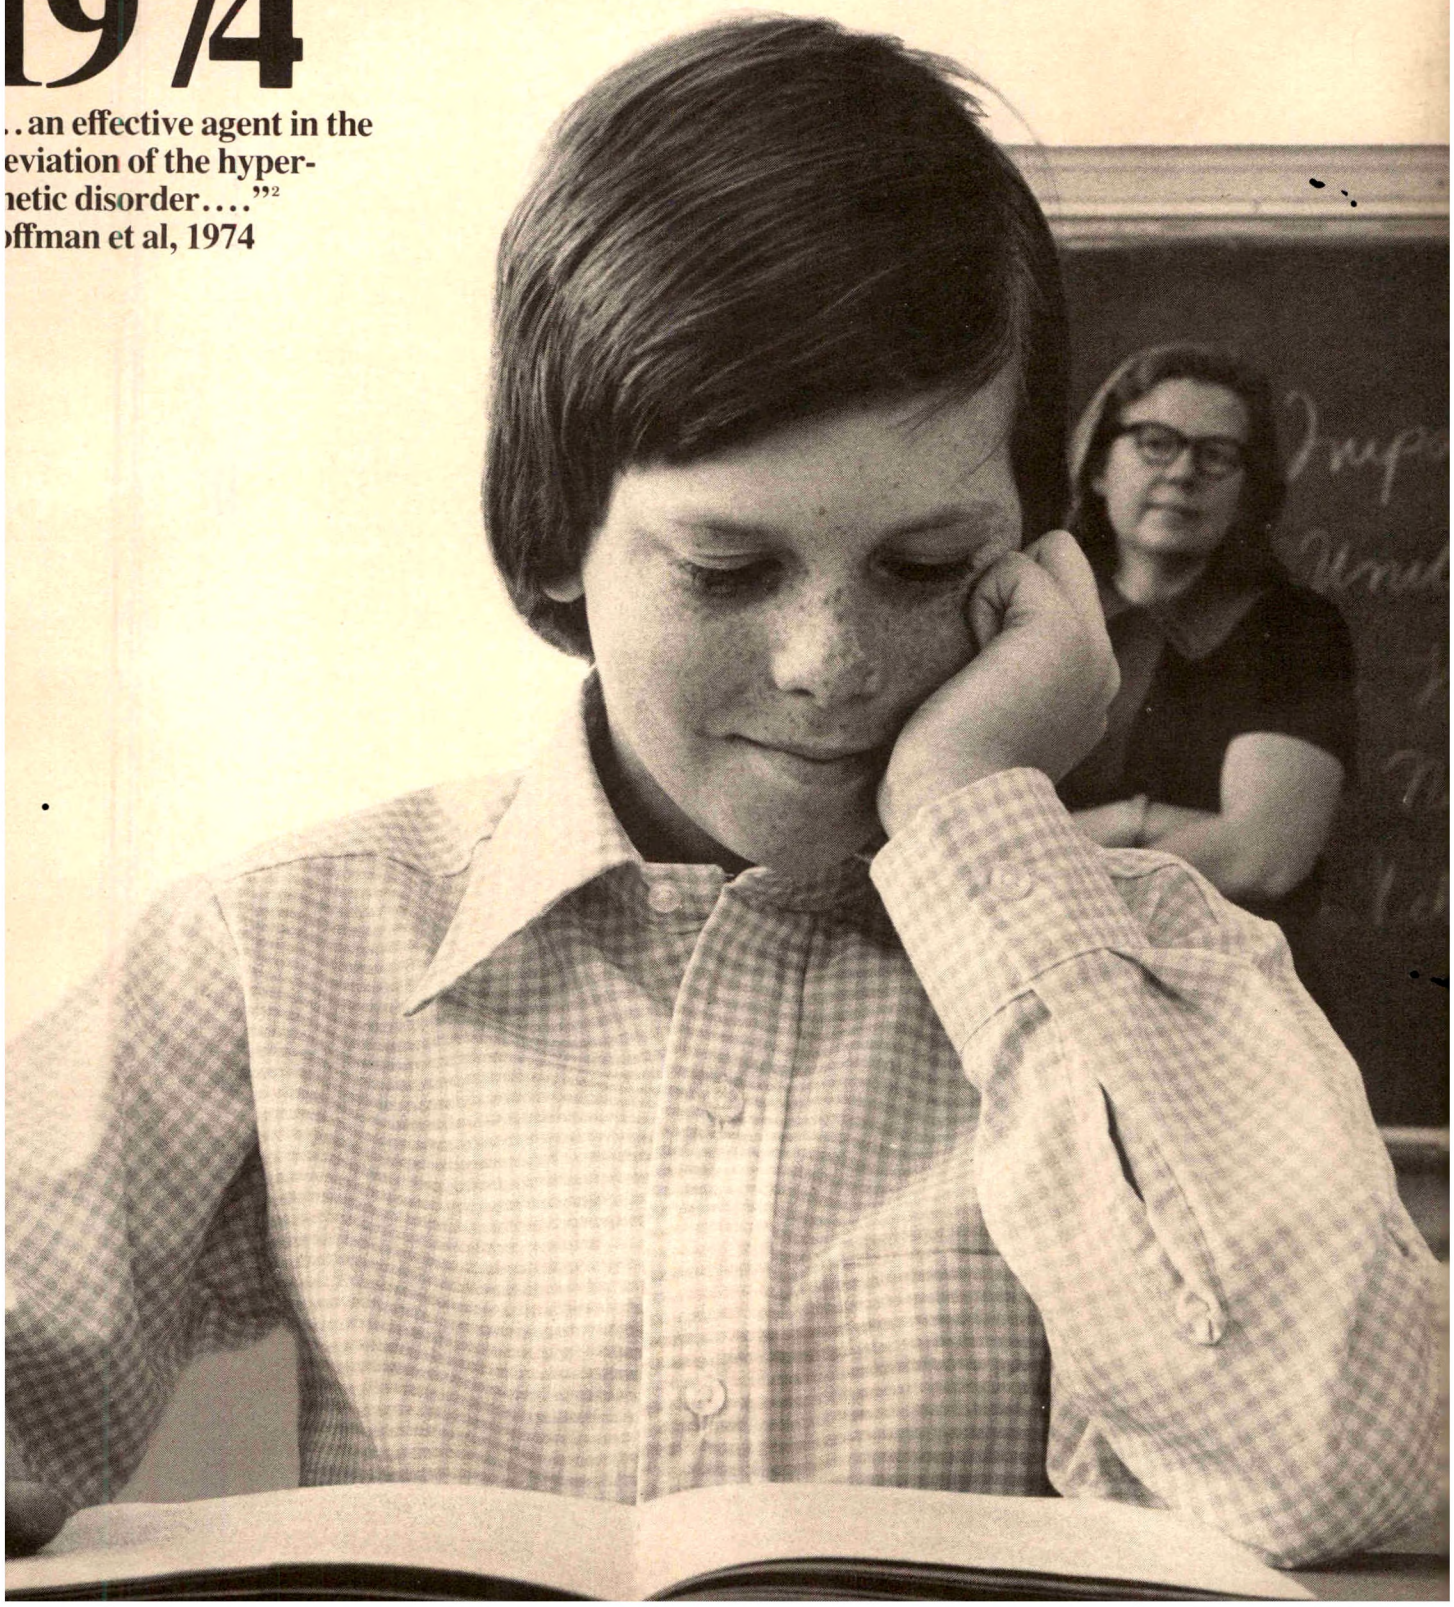
Over a decade of controlled studies and clinical experience has shown the effectiveness of Ritalin in reducing the hyperactivity,[1-3] distractibility,[1,4,5] and disorganized behavior[1-8] in the MBD child.

By lessening the effects of motor and attentional disorders, Ritalin can help the MBD child to better focus his attention on meaningful stimuli and thus can often improve cognition and promote learning.[6,9]

And side effects – insomnia a appetite loss – with Ritalin have occurred less frequently than witl dextroamphetamine.[10,11]

Indeed, Ritalin is currently a drug of choice in many MBD situa tions,[10,12] and can prove to be an im portant element in many complete remedial programs for MBD.

Therapy with Ritalin should l undertaken only after a medical diagnosis of MBD has been made. Drug treatment is not indicated fo all children with MBD.



Dosage should be periodically interrupted. Often, these interrup tions reveal some "stabilization" in the child's behavior even without medication, permitting a reductior in dosage and eventual discontinuance of drug therapy.

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak® blister units of 100

Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

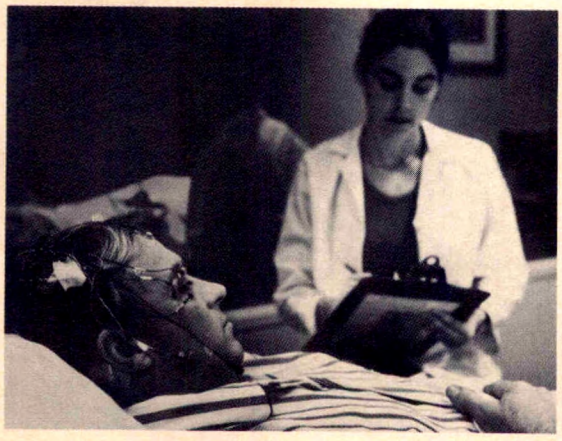
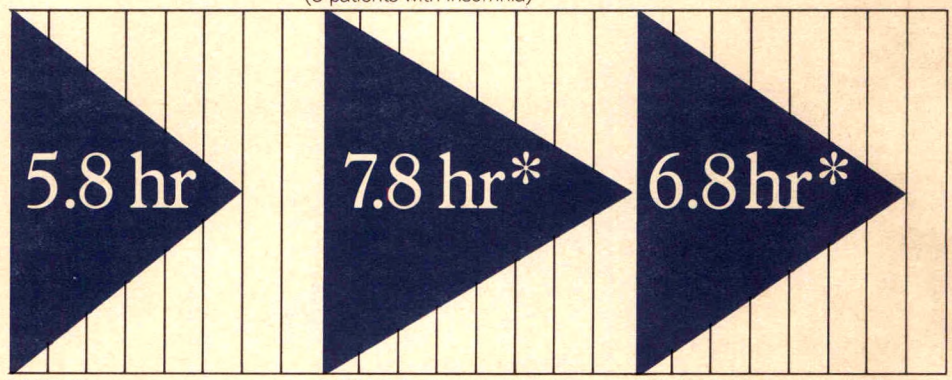
From the sleep research laboratory:



Dalmane® (flurazepam HCl) proved the most effective hypnotic over 14 nights...[1]

14 consecutive nights:
3 in sleep laboratory, 8 at home,
3 in sleep laboratory

...and now, the only one proved effective over 28 nights.[2,3]



28 consecutive nights:
3 in sleep laboratory, 7 at home,
4 in sleep laboratory, 10 at home,
4 in sleep laboratory[3]

For those patients who need it, Dalmane (flurazepam HCl) alone provides continued effectiveness[2,3]

Since insomnia is often transient and intermittent, the prolonged administration of a hypnotic is generally not necessary or recommended. But for those patients whose insomnia is a chronic problem, the continued effectiveness of Dalmane is a decided benefit. Even at the end of a 28-night medication period, patients with chronic insomnia were falling asleep faster, spending less time awake during the night, and sleeping substantially longer on Dalmane 30 mg *h.s.* than on baseline placebo nights (average results). This effectiveness was proved[2] and confirmed[3] in two independent sleep research studies using a new 47-night protocol. When similarly evaluated, pentobarbital was ineffective at the end of two weeks.[2]

TOTAL SLEEP TIME (MEAN)[3]
(5 patients with insomnia)

*Significantly increased over baseline placebo ($P < .05$).

In previous studies[1], chloral hydrate and glutethimide lost most or all effectiveness

In fact, continued effectiveness for both inducing and maintaining sleep over 14 consecutive nights[1] has long been an exclusive benefit of Dalmane. No other available sleep agent, including chloral hydrate or glutethimide,[1] has been able to demonstrate such effectiveness in the sleep research laboratory.

The safety record of Dalmane (flurazepam HCl) is well established

Dalmane is relatively safe and well tolerated. Prolonged administration is not generally necessary, but if used repeatedly, periodic blood counts and liver and kidney function tests should be performed.

Dalmane®
(flurazepam HCl)

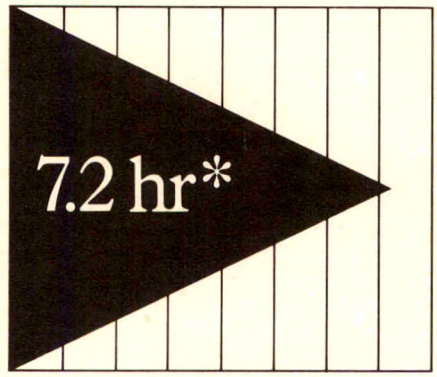
ROCHE

relatively safe... no need to increase dosage.

Please see following page for a summary of complete product information.

1,5,7,14,28 nights... as needed, the effectiveness of **Dalmane**® one *h.s.* (flurazepam HCl) Ⓒ IV meets the challenge of insomnia

One 30-mg capsule *h.s.*—usual adult dosage (15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.



■ Patients fall asleep rapidly, sleep longer on a single *h.s.* dose.

■ Nighttime awakenings and time spent awake are reduced

■ Effectiveness maintained without dosage increase from night to night

■ Patients generally awaken refreshed; morning "hangover" is infrequent

TOTAL SLEEP TIME (OVERALL MEAN)[3]
(5 patients with insomnia)

DALMANE (flurazepam HCl)
NIGHTS 1-3, 12-14, 26-28

Before prescribing Dalmane (flurazepam HCl), please consult complete product information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

Where The Action Is—

For more than a decade the general hospital psychiatric unit has been the principal locus of inpatient treatment. This latest Joint Information Service national survey brings up to date its earlier—and the original—study of this important component of the psychiatric scene. It reveals that the remarkable rate of growth held up, showing an increase of 50 percent in the number of units between 1963 and 1971, and an increase of 46 percent in the number of admissions. And it verifies that general hospital psychiatry has become increasingly comprehensive, with an impressively high level of outpatient service, emergency service, and even consultation to community agencies. Indeed, the general hospital accounts for several times as much service and activity as the widely heralded federally supported community mental health center.

This study also involves the private psychiatric hospitals, which have not changed much in number but are admitting about 10,000 more patients than in 1964—and they, too, are providing a remarkably comprehensive program.

It's your responsibility to be well-informed about these extraordinarily significant and vital pieces of American psychiatric service. You can do so by sending the order form below.

in clinically significant depression...

penetrating the symptom barrier to productive psychotherapy

symptoms often interfere with therapy

In clinically significant depression, the patient often becomes barricaded behind his own symptoms during psychotherapy. Because these symptoms can be so sharply defined and somatic in expression, he may reject the fact that they are psychic in origin. Sleep disturbance, gastrointestinal complaints, anorexia, chronic fatigue, and other psychosomatic symptoms may so preoccupy—or overwhelm—the depressed patient that truly productive therapeutic sessions are difficult to achieve. Instead of being able to concentrate on the core emotional problems of the depression itself, he may for example go on at length about how broken his sleep is or keep reiterating (while the therapeutic hour slips by) how physically miserable he feels.

ELAVIL®
(AMITRIPTYLINE HCl, MSD)
to help penetrate the symptom barrier in depression requiring medication

ELAVIL, a highly effective tricyclic antidepressant, will often alleviate these symptoms. With the help of ELAVIL, sleep disturbance—so common in clinically depressed patients and often the symptom that distresses them most—as

well as other "barrier symptoms" may be lessened to the point where they no longer come between you and the patient.

psychotherapy takes direction

As these preoccupying complaints are lifted, psychotherapy sessions can become more productive. Patients are enabled to respond more fruitfully during therapeutic hours and to resume or pursue more efficiently the necessary activities in their personal lives.

meeting therapeutic goals

And as the antidepressant activity of ELAVIL (Amitriptyline HCl, MSD) takes hold, it helps relieve the depressive condition itself. Sometimes only a minimum of actual psychotherapy is required. The patient may experience a more rapid recovery—while you conserve valuable time.

Prescribe ELAVIL then, to help lighten the patient's burden in depression—and yours in its management.

ELAVIL should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Its safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

TABLETS: 10 mg, 25 mg, 50 mg, 75 mg, and 100 mg
INJECTION: 10 mg per ml

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

an antidepressant with an anxiety-reducing sedative component to its action

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information, please see following page.

MSD
MERCK SHARP & DOHME

addendum

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

Five tablet strengths for differing patient needs. The variety of dosage strengths available with ELAVIL makes possible great prescribing flexibility.

Once-a-day dosage at bedtime is an appropriate way to start—and maintain—many patients on therapy. The simplicity of this regimen helps improve patient compliance. ELAVIL may also be prescribed in divided daily doses.

A sedative effect may be apparent before the antidepressant effect of ELAVIL is noted. An adequate therapeutic effect may take as long as 30 days to develop.

100 mg
75 mg
50 mg

These tablets may be advantageous when initiating therapy with once-daily bedtime dosage in adult outpatients. The usual starting dosage is 75 mg daily. Therapy may be initiated with 50 to 100 mg daily. This may be increased by 25 or 50 mg as necessary in the bedtime dose to a total of 150 mg per day.

These tablets may also be convenient for many hospitalized patients. These patients may need 100 mg a day initially which can be increased gradually to 200 mg a day if necessary. A small number of such patients may need as much as 300 mg a day.

25 mg

This tablet may prove useful when initiating therapy with divided daily doses in adult outpatients. Starting dosage is usually 75 mg daily. If necessary, this dosage may be increased gradually to a total of 150 mg a day. Increases are made preferably in the late afternoon or bedtime doses.

10 mg

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher doses.

NOTE: The usual maintenance dosage of ELAVIL is 50 to 100 mg per day which may be given in a single dose preferably at bedtime. In some patients 40 mg per day is sufficient. This drug is not recommended for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required; paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported. Use with caution in patients with impaired liver function.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue, rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; tablets containing 75 mg and 100 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486

MSD
MERCK SHARP & DOHME

The George Washington University Medical Center is seeking a Chairperson of the Department of Psychiatry and Behavioral Science. The Department has a full time faculty of 10 persons, and a large voluntary faculty throughout the metropolitan Washington area. Resources include a 33 bed unit within the University Hospital, an ambulatory facility caring for 10,000 visits per year, a substantial research program centered on family therapy and drug and alcohol abuse, a training program to include 6 residents per year, and extensive input into each of the 4 years of the medical school curriculum. Capacity to develop liaison with Washington psychiatric community and mental health resources is a Medical Center priority. Applicant should have significant experience in administration in a medical school or related programs. Write Thomas E. Piemme, M.D., Chairman, Search Committee, 1229 25th Street, N.W., Washington, D.C. 20037. An equal opportunity employer.

Position Available Immediately

Board Certified Psychiatrist

Full time 40 hours per week. Emergency service on-call availability. Out-patient psychiatric services, all ages. Approximate maximum salary $42,000 depending on qualifications.

LIFT THE MASK OF SCHIZOPHRENIC SYMPTOMS

'Stelazine' provides effective control of hallucinations, delusions, anxiety and other psychotic symptoms.
With its apparent activating effect, 'Stelazine' is especially useful in withdrawn, apathetic or detached patients.

- Controls psychotic symptoms
- Seldom causes excessive sedation
- Convenient b.i.d. dosage

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications
Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

'Stelazine' has not been shown effective in the management of behavioral complications in patients with mental retardation.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F*) or other phenothiazines:* Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg., and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only) 10 mg./ml.

TRIFLUOPERAZINE HCl

Helps schizophrenic patients become more responsive.

Drunken driving is the cause of an estimated 28,000 auto accident deaths each year—approximately half of these fatal accidents involve an alcoholic. This is only one aspect of the staggering problem represented by alcoholism—perhaps this country's most neglected disease.

Yet, it needn't be, for alcoholism is treatable. Through early detection and treatment of the alcoholic, as well as the use of community resources, physicians can exert a major force in the control and reduction of alcoholism.

ANTABUSE (disulfiram) can help. It offers strong deterrent action...helping alcoholic patients maintain a state of sobriety, while they participate in a total treatment program. Your patient should know the consequences of even a single drink while taking this medication. ANTABUSE works by blocking the normal degradation of alcohol, sharply increasing the concentration of acetaldehyde in the blood by 5 to 10 times, and setting off a most unpleasant, though temporary reaction.

ANTABUSE helps strengthen your patient's resolve...while you help with his underlying problem. On ANTABUSE therapy, the alcoholic patient functions more effectively—not only behind the wheel, but also at work and at home.

BRIEF SUMMARY
(For full prescribing information, see package circular.)
ANTABUSE® (disulfiram) In Alcoholism
INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)
CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, e.g. cough syrups, tonics, and the like, should not be given ANTABUSE.
ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.

WARNINGS: ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.
The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.
THE ANTABUSE-ALCOHOL REACTION:
ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.
The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.
The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.
DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.
Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.
It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.
Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.
CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.
USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.
PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)
Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.
Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.
ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)
Optic neuritis, peripheral neuritis, and polyneuritis may occur following administration of ANTABUSE.
Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.
In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.
Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.
One case of cholestatic hepatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.
DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.
INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.
MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.
NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE, report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.
DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years.
TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, such a test reaction should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.
However, where a test reaction is deemed necessary, the suggested procedure is as follows:
After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (1/2 oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops, no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.
MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokalemia has been reported.
HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100.
No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000. **7626**

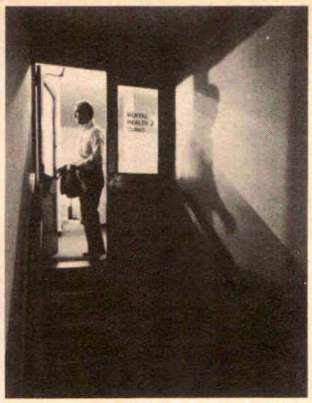
Haldol®
(haloperidol)
tablets/concentrate/injection

For long-term control with minimal risk of toxicity

Highly effective in a wide range of psychotic symptoms,[1-7] such as hallucinations, delusions, suspiciousness, hostility, mania, psychomotor agitation, etc., in both acute and chronic disorders.

Usually leaves patients relatively alert and responsive...[1-3] better able to cope with job and family responsibilities...as well as easier to reach with supportive and rehabilitative measures.

Permits aggressive titration to effective dosage levels,[1,4] up to 100 mg/day orally (with minimal risk of usual troublesome reactions) to achieve optimal response when patient is inadequately controlled at lower dosage...to help you rapidly control and stabilize new patients, promptly regain control during periods of exacerbation.



Common side effects easily controlled.[1,3-6] Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Reduces risk of certain troublesome reactions.[2-5,7] Transient hypotension occurs rarely and severe orthostatic hypotension has not been reported. Marked sedation is rare, although some instances of drowsiness have been reported. In addition, with chronic use, it is unlikely to cause hepatic damage, serious hematologic reactions, photosensitivity reactions and skin rashes...and has minimal effect on renal function.

Please turn page for information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions.

Important: Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

Haldol® (haloperidol)

tablets/concentrate/injection

For long-term control of psychotic symptoms with minimal risk of toxicity

A Dosage Form for Every Need:

5 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg., 5 mg. and 10 mg.

A tasteless, odorless, colorless liquid concentrate for better patient acceptability: 2 mg. per ml.

A rapid-acting injection for psychiatric emergencies: 5 mg. per ml., with 1.8 mg. methylparaben and 0.2 mg. propylparaben per ml., and lactic acid for pH adjustment to 3.4±0.2.

Indications: HALDOL haloperidol is indicated for use in the management of manifestations of psychotic disorders.

It is also indicated for the control of tics and vocal utterances of Gilles de la Tourette's syndrome.

Contraindications: HALDOL haloperidol is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy:*** Safe use of HALDOL haloperidol in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of haloperidol orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children: Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL haloperidol, decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL haloperidol may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL haloperidol should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL haloperidol may lower the convulsive threshold. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant antiparkinson medication is required, it may have to be continued after HALDOL haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson agents, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of antiparkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Persistent Tardive Dyskinesia*—Tardive dyskinesia may appear during long-term therapy or after therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. There is no known effective treatment. All antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL haloperidol is administered or prescribed. 9/74

ADAPIN®
(Doxepin HCl)

Capsules, 10 mg., 25 mg., 50 mg.

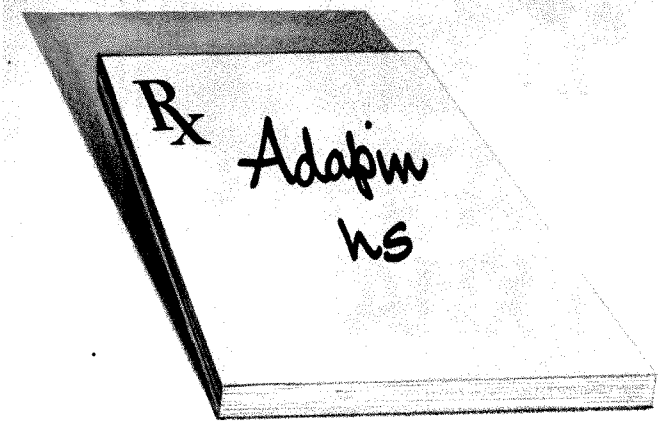
And the Management of Disturbed Sleep Patterns in Anxiety/Depression

Disturbed sleep patterns are a familiar component of the symptom complex seen in patients with anxiety and/or depression.

One study[1] has shown that doxepin [Adapin] is helpful in providing symptomatic relief of sleep disturbances associated with anxiety and depression, "allowing patients to fall asleep more rapidly and feel more rested upon awakening."

Another study[2] points out that doxepin [Adapin] given "at bedtime to outpatients with mixed anxiety and depression will yield as much improvement as can be obtained by giving the drug three times a day."

So, a single dose of Adapin, given at bedtime can often help promote a restful night's sleep for patients with mixed anxiety and depression. Other clinical benefits include:



- rapid antianxiety effect
- distinct clinical brightening of mood—usually within three to four weeks
- low incidence of side effects
- suitability for long-term usage

ADAPIN®

(Doxepin HCl)

Prescribing information:

DESCRIPTION

Adapin (doxepin HCl) is an isomeric mixture of N, N-dimethyl-dibenz(b,e) oxepin- $\Delta^{11(6H)}$, γ propylamine hydrochloride.

ACTIONS

Adapin has a variety of pharmacological actions with its predominant action on the central nervous system. While its mechanism of action is not known, studies have demonstrated that it is neither a monoamine oxidase inhibitor nor a primary stimulant of the central nervous system.

INDICATIONS

In controlled clinical evaluations, **Adapin** has shown marked antianxiety and significant antidepressant effects. **Adapin** has been found to be well tolerated even in elderly patients.

Adapin is indicated for the treatment of patients with:

1. Psychoneurotic anxiety and/or depressive reactions.
2. Mixed symptoms of anxiety and depression.
3. Anxiety and/or depression associated with alcoholism.
4. Anxiety associated with organic disease.
5. Psychotic depressive disorders including involutional depression and manic-depressive reactions.

Target symptoms of psychoneurosis that respond particularly well to **Adapin** include: anxiety, tension, depression, somatic symptoms and concerns, insomnia, guilt, lack of energy, fear, apprehension and worry.

Because **Adapin** provides antidepressant as well as antianxiety effects, it is of particular value in patients in whom anxiety masks depression. Patients who have not responded to other antianxiety or antidepressant drugs may benefit from **Adapin.**

In a large series of patients systematically observed for withdrawal symptoms, none were reported—a finding which is consistent with the virtual absence of euphoria as a side effect and the lack of addictive potential characteristic of this type of chemical compound.

CONTRAINDICATIONS

Because **Adapin** has an anticholinergic effect, it is contraindicated in patients with glaucoma or a tendency toward urinary retention.

Use of **Adapin** is contraindicated in patients who have been found hypersensitive to it.

WARNINGS

Usage in Pregnancy—Adapin has not been evaluated in pregnant patients. Therefore, it should not be used during pregnancy unless, in the judgment of the physician, it is essential to the welfare of the patient.

In animal reproduction studies of **Adapin (doxepin hydrochloride),** gross and microscopic examination of the offspring gave no evidence of drug-related teratogenic effect. Following doses of up to 25 mg./kg./day for 8 to 9 months, no changes were observed in the number of live births, litter size, or lactation. A decreased rate of conception was observed when male rats were given 25 mg./kg./day for prolonged periods—an effect which has occurred with other psychotropic drugs and has been attributed to drug effect on the central and/or autonomic nervous systems.

Usage in Children—The use of **Adapin** in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors—Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with **Adapin.** The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

PRECAUTIONS

Drowsiness may occur with **Adapin;** therefore, patients should be warned of its possible occurrence and cautioned against driving a motor vehicle or operating hazardous machinery while taking the drug.

Patients should also be cautioned that the effects of alcoholic beverages may be increased.

Since suicide is an inherent risk in depressed patients and remains a risk through the initial phases of improvement, depressed patients should be closely supervised.

Although **Adapin** has shown effective tranquilizing activity, the possibility of activating or unmasking latent psychotic symptoms should be kept in mind.

Compounds structurally related to **Adapin** can block the effects of guanethidine and similarly acting compounds. However, at the usual clinical dosages, 75 mg. to 150 mg. per day, **Adapin** has been given concomitantly with guanethidine without blocking its antihypertensive effect. But at dosages of 300 mg. per day or higher, **Adapin** has exerted a significant blocking effect.

Adapin, like other structurally related psychotropic drugs, potentiates norepinephrine response in animals. But this effect has not been observed with **Adapin** in humans, which is in accord with the low incidence of tachycardia reported clinically.

ADVERSE REACTIONS

Anticholinergic Effects: Dry mouth, blurred vision and constipation have been reported. These are usually mild, and often subside as therapy is continued or dosage reduced.

Central Nervous System Effects: Drowsiness has been observed. It usually occurs early in the course of therapy and tends to subside as therapy continues. (See Dosage and Administration section.)

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported adverse effects include extrapyramidal symptoms, gastrointestinal reactions, secretory effects (such as increased sweating), weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

DOSAGE AND ADMINISTRATION

In most patients with mild to moderate anxiety and/or depression: 10 mg. to 25 mg. t.i.d. to start. A starting dosage of 10 mg. t.i.d. for a period of four days may reduce the initial drowsiness experienced by some patients, and may be tried in cases where drowsiness is clinically undesirable. Decrease or increase the dosage at appropriate intervals according to individual response. Usual optimum dosage is 75 mg. to 150 mg. per day.

In some patients with mild symptomatology or emotional symptoms accompanying organic disease, dosage as low as 25 mg. to 50 mg. per day has provided effective control.

In more severe anxiety and/or depression: 50 mg. t.i.d. may be required to start—if necessary, gradually increase to 300 mg. per day. Additional effectiveness is rarely obtained by exceeding 300 mg. per day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

OVERDOSAGE

Symptoms—An increase of any of the reported adverse reactions, primarily excessive sedation and anticholinergic effects such as blurred vision and dry mouth. Other effects may be: pronounced tachycardia, hypotension and extrapyramidal symptoms.

Treatment—Essentially symptomatic; supportive therapy in the case of hypotension and excessive sedation.

HOW SUPPLIED

Each capsule contains doxepin, as the hydrochloride, 10 mg. (NDC 0018-0356), 25 mg. (NDC 0018-0357), and 50 mg. (NDC 0018-0358) capsules in bottles of 100 and 1000.

Just published
4th edition

A Psychiatric Glossary

Edited by a subcommittee of the AMERICAN PSYCHIATRIC ASSOCIATION Committee on Public Information.

The new Fourth Edition marks a striking expansion of definitions: 400 terms have been added and many of the terms appearing in earlier editions have received revised explanations. In addition to the GLOSSARY's continuing value to lawyers, teachers, journalists, social workers, and others, the new edition will be useful to medical students and first year residents in psychiatry.

Some major changes in the Fourth Edition:

- Expansion from 102 to 156 pages to accommodate 400 new terms
- New tables of terms in seven areas of contemporary concern
  - Drugs Used in Psychiatry
  - Legal Terms
  - Neurologic Deficits
  - Psychological Tests
  - Research Terms
  - Schools of Psychiatry
  - Sleep Disorders
- A comprehensive set of terms used in behavior therapy is included for the first time.

Paperback edition—$3.00 each, (See coupon for bulk discounts), may be ordered from the AMERICAN PSYCHIATRIC ASSOCIATION, Publications Sales, 1700 18th St. N.W., Washington, D.C. 20009.

Hardback edition—$7.95 may be ordered from Basic Books, Inc., 10 East 53rd Street, New York, New York 10022.

LIBRIUM®
(chlordiazepoxide HCl)
5 mg, 10 mg, 25 mg capsules

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.
Contraindications: Patients with known hypersensitivity to the drug.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.
Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.
Supplied: Librium® Capsules containing 5 mg, 10 mg, or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

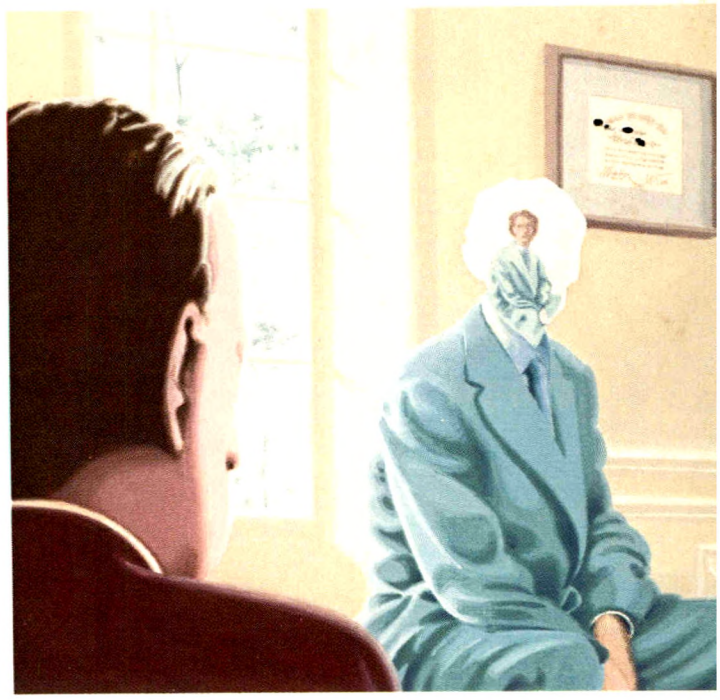
EXPERIENCE. CONSISTENT EFFICACY IN REDUCING "ANXIETY BLOCK."



During the entry phase of psychotherapy, heightened levels of obstructive anxiety are often encountered. At such times, the dependable antianxiety action of Librium can effectively facilitate verbal communication, helping to foster a more productive relationship between patient and physician—usually without impairing mental acuity.

A consistent pattern of patient response

As treatment progresses and disturbing psychologic material is brought to the surface, anxiety may again rise sharply, creating patient resistance to further exploration. During this probe phase, adjunctive Librium has demonstrated its ability to relieve excessive anxiety and help the patient handle his emerging insights—especially as he seeks to apply those hard-won insights in his daily life.

A highly favorable benefits-to-risk ratio

The most common side effects of Librium are dose-related and thus largely avoidable. There appears to be a low incidence of drug dependence and tolerance. Librium rarely has been reported to have an adverse effect on the cardiovascular or respiratory system and is used concomitantly with many primary medications.

As with all CNS-acting agents, patients taking Librium should be cautioned against hazardous activities requiring complete mental alertness, and against combined effects with alcohol and other CNS depressants. Once anxiety has been reduced to manageable levels, Librium should be discontinued.

trifluoperazine HCl
in Psychiatry."

Messenger Mask, Dene culture, Anvik, Alaska. Festival mask representing legendary cannibal woman's son who lured victims for his mother.

From the collection of the University Museum, University of Pennsylvania, Philadelphia, Pa. Reproduced with permission.

REMOVE THE MASK OF SCHIZOPHRENIC SYMPTOMS

'STELAZINE' PROVIDES EFFECTIVE CONTROL OF HALLUCINATIONS, DELUSIONS, ANXIETY AND OTHER SCHIZOPHRENIC SYMPTOMS IN A WIDE RANGE OF PATIENTS.

FROM THE WITHDRAWN AND APATHETIC TO THE ANXIOUS AND OVERACTIVE, 'STELAZINE' HELPS RETURN THE PSYCHOTIC PATIENT TO REALITY AND CAN FACILITATE THERAPEUTIC CONTACT AND RAPPORT.

- EFFECTIVELY CONTROLS PSYCHOTIC SYMPTOMS
- SELDOM CAUSES EXCESSIVE SEDATION
- CONVENIENT B.I.D. DOSAGE

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications
Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

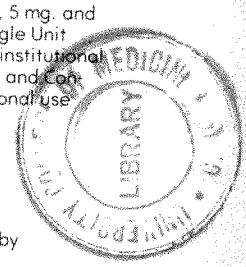
'Stelazine' has not been shown effective in the management of behavioral complications in patients with mental retardation.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.



Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only) 10 mg./ml.

The Rape Victim

by Elaine Hilberman, M.D.

Mythologies about rape are legion. However, in recent years behavioral scientists have accumulated a body of information about rape and about an unfolding series of reactions experienced by the victim after rape. The aim of this concise, tightly reasoned book is to summarize what is now known about the needs and experiences of the victim and her family, and to provide a framework in which the clinician can more knowledgeably supply assistance and support. This document, published by the American Psychiatric Association, is the result of a project of the Association's Committee on Women.

Pointing out that the profound impact of rape stress is best understood in the context of rape as "a crime against the person and not the hymen," Dr. Hilberman sees rape as the ultimate violation of the self short of homicide, as an act of violence and humiliation in which not only is the victim's very existence threatened, and her inner and most private space invaded, but her autonomy and control are totally demolished. Dr. Hilberman shows that if and when the victim reports the crime, she is confronted with a complex series of yet additional stresses growing out of her contact with the hospital, police, courts, media and community opinion. Additionally, her crisis differs from other crises in that her usual social support system is likely to be disrupted. Her immediate needs are for empathy and safety, and a sense of control over what is happening in her dealings with the several agencies. Dr. Hilberman shows that in the absence of sensitivity to these needs, the experience of reporting becomes another assault.

This book presents a professional, sobering, and balanced picture of the problems of the rape victim and details what the clinician must know—about local hospital policy, criminal justice procedure, rape statutes, and community attitudes and services—in order to be able to treat victims with an understanding of the larger context in which rape occurs.

ELAINE HILBERMAN, M.D., *is in the Department of Psychiatry at the University of North Carolina School of Medicine.*

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone, should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; with other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there will usually be a charge for granting this permission.

Informed consent. Manuscripts that report the results of experimental investigation on human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure had been fully explained.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

All measurements must be in metric units.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal's* Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed 8 typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the coauthor who has been designated to assume responsibility for the paper and reprint requests. The number of authors should be limited to principal researchers and writers, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the syle used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Tables and figures should be self-explanatory and should supplement, not duplicate, the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the paper. Most figures will be reduced to about 3¼ inches in width; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHORS' CORRECTIONS

After the paper has been scheduled for publication, the edited manuscript will be sent to the first-named author for corrections and answers to queries. Prompt return is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after being notified of the acceptance of his paper, he should inform the *Journal* office or arrange with a coauthor to assume responsibility for the paper. Galley proofs will not be sent to authors.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

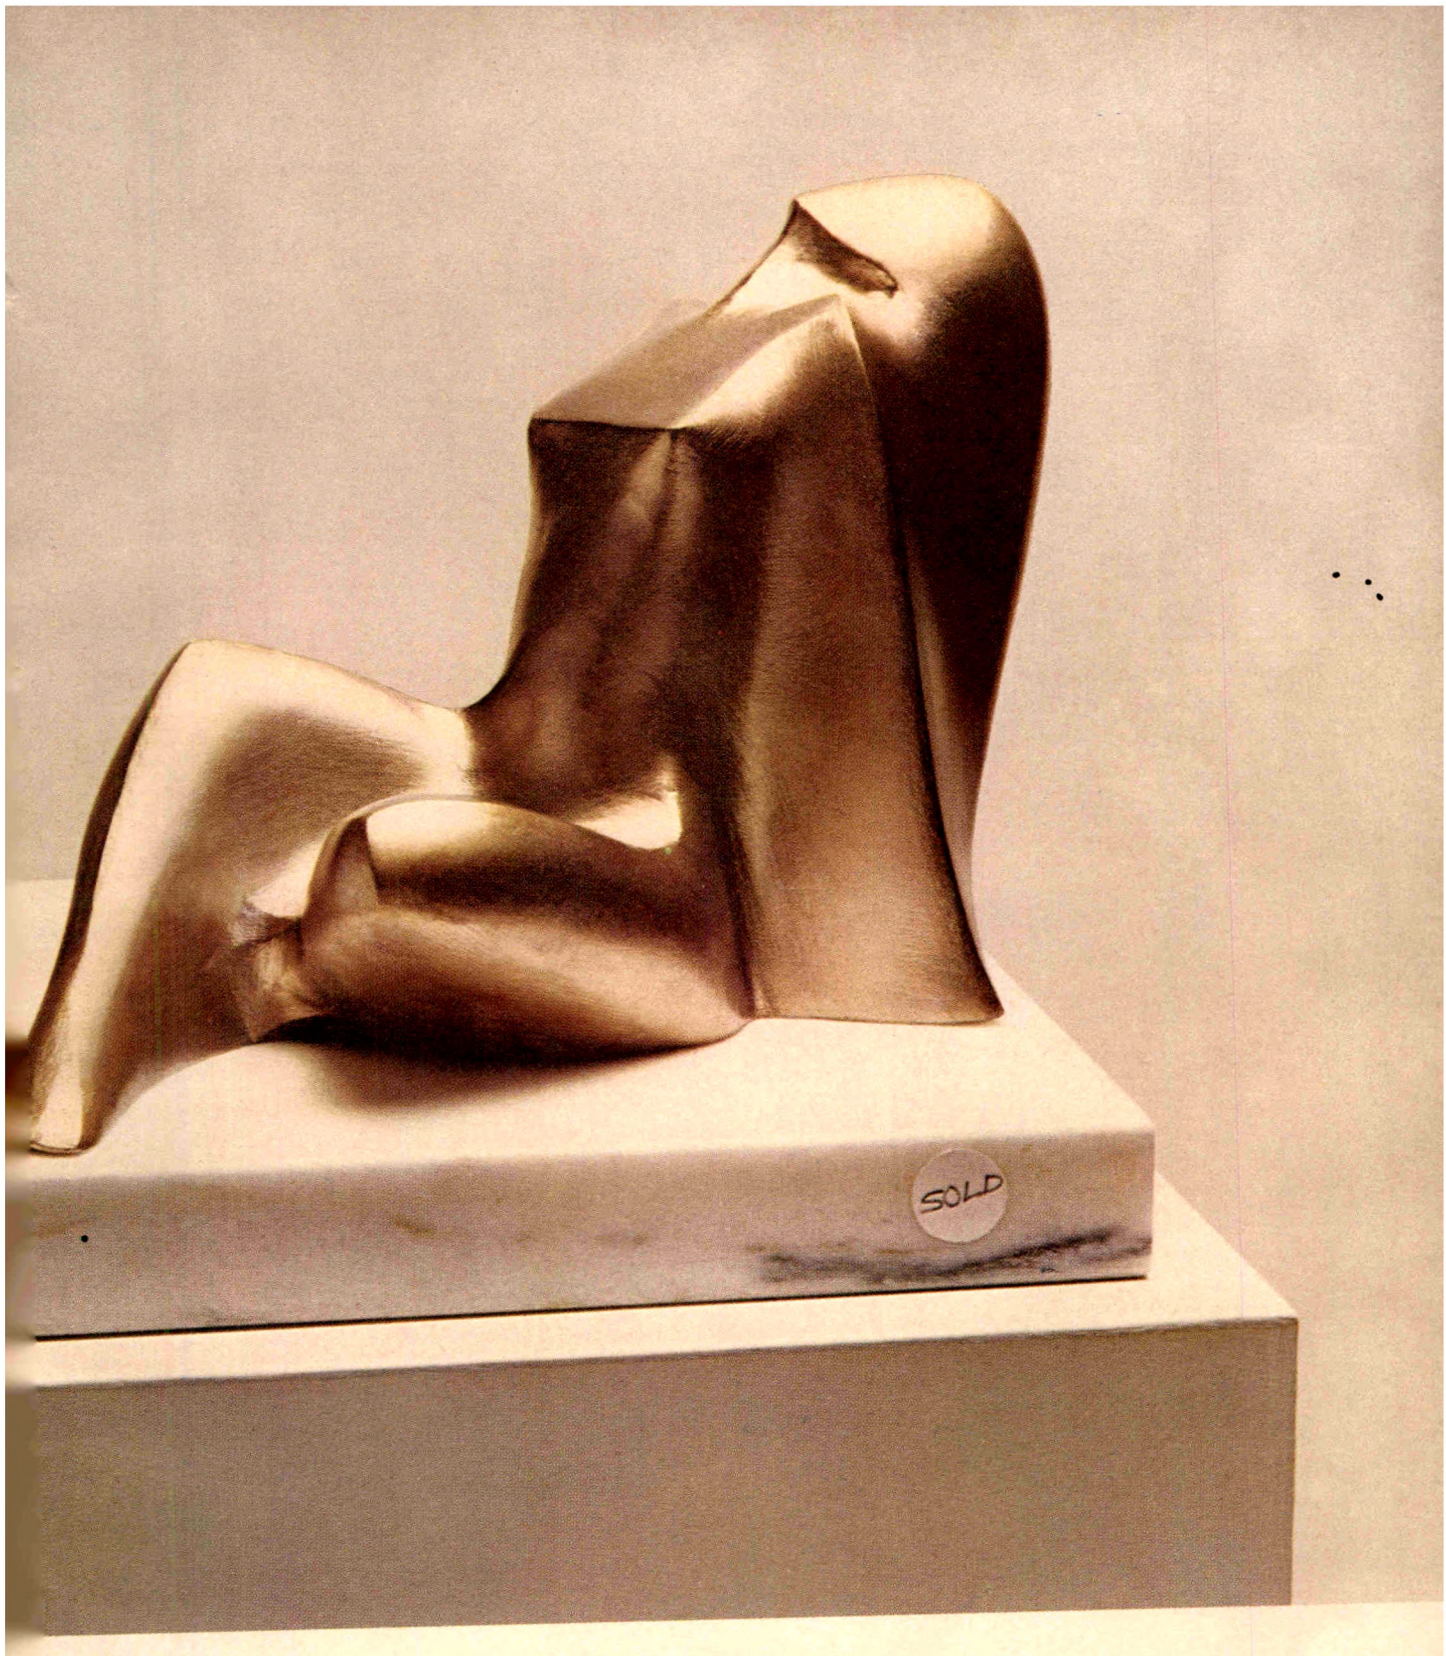
Released from symptoms of psychotic depression...

Productive again.



By helping to reduce the frequency and intensity of psychotic symptoms, Navane (thiothixene) often permits resumption of more normal, more productive living.

The antipsychotic effectiveness of Navane—with relatively little drowsiness—helps patients remain more active, more alert, better able to meet the ordinary demands of life.

Cardiovascular side effects such as hypotension and nonspecific EKG changes are relatively rare with Navane (thiothixene). Extrapyramidal symptoms have been reported, but are usually controlled by reduction in dosage and/or administration of antiparkinson drugs.

Once you've controlled acute psychosis or psychotic depression, some patients can be maintained on a simple once-a-day dose. This once-a-day regimen can reduce the risk of missed doses with no loss of efficacy.

Navane® (thiothixene)
Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg (thiothixene hydrochloride) Concentrate: 5 mg/ml, Intramuscular: 2 mg/ml

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children–The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration – As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution–For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate–In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor elevating action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg. of thiothixene in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

Dome

New program for more than symptomatic control of the schizophrenic...

new from Dome Laboratories: a dual approach to help the schizophrenic adjust to a more normal life

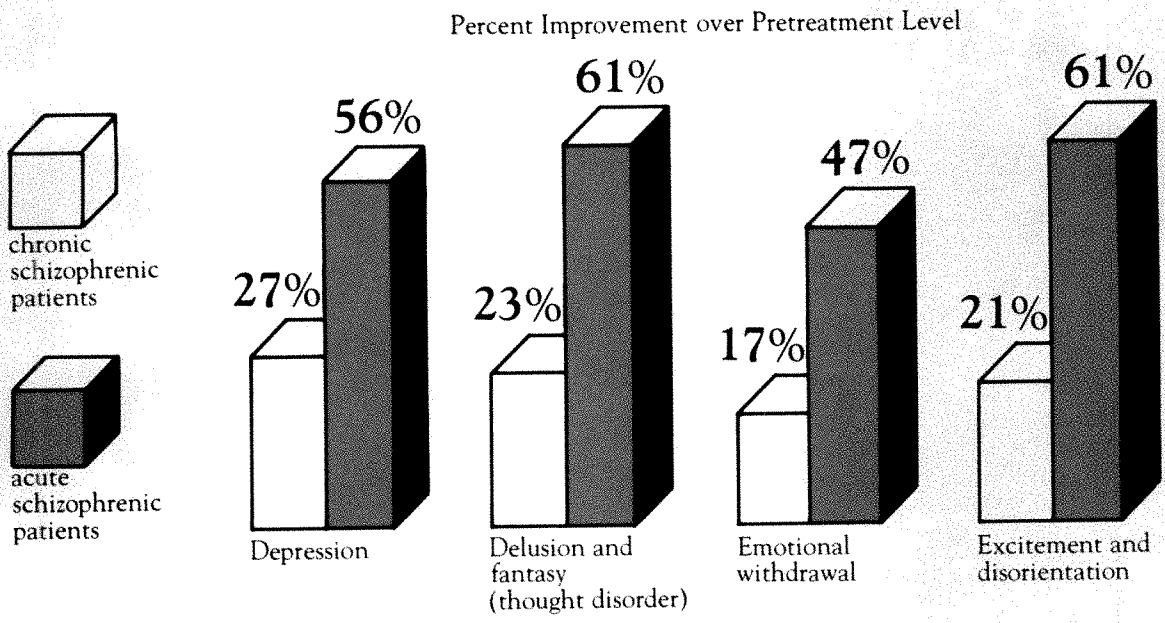
first... symptomatic help for the schizophrenic

Daxolin™
(loxapine succinate)

extensively investigated clinically

Loxapine succinate [Daxolin] has been studied clinically in both chronic and acute schizophrenic patients for over six years.[1-11]

evaluated by psychiatrists—BPRS (Brief Psychiatric Rating Scale), CGI (Clinical Global Impression)



evaluated by psychiatric nurses—NOSIE (Nurse's Observation Scale for Inpatient Evaluation)

evaluated by patients—SRSS (Self-Rating Symptom Scale)

compared with various other agents including chlorpromazine, trifluoperazine, doxepin, thiothixene, as well as placebo—from 11 published, controlled/double-blind studies involving 482 patients[1-11]

helps control symptoms of acute and chronic schizophrenia.

Evaluation (by BPRS) of symptomatic response in 221 chronic and acute schizophrenic patients[12]

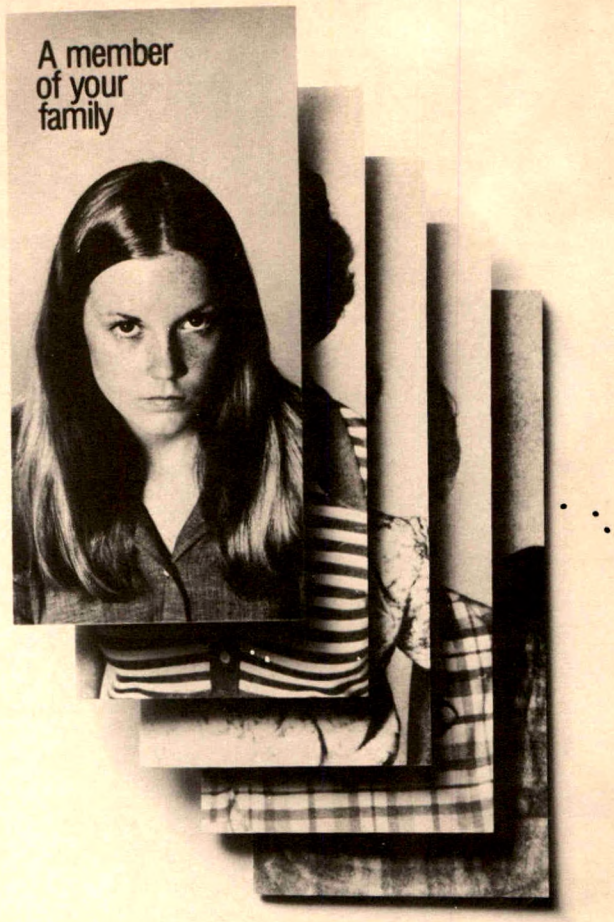
- ☐ significant improvement noted in behavior patterns, severity of symptoms significantly reduced
- ☐ helps control major target symptoms in responsive patients
- ☐ dosage strengths to meet individual needs
- ☐ adverse CNS manifestations—other than extrapyramidal reactions—infrequent*

***See "Adverse Reactions" section in the prescribing information on last page.**

and...

second... help for those close to the schizophrenic

EMP (EMPATHIC) COMMUNICATIONS



The symptoms of schizophrenia can be bizarre and puzzling—especially to family and others in close contact with the patient. To help them understand the disease, and thus be more helpful to the patient, Dome Laboratories offers *EMP* (Empathic) *Communications,* a comprehensive new education program developed especially for lay readers.

By providing authoritative, easy-to-understand booklets, this program encourages family and friends to cooperate in the patient's adjustment to therapy and rehabilitation.

...and for your information

PSYCHIATRIC INTERFACES

A new and ongoing publication of firsthand information that deals with current psychiatric trends and offers opinions on mental-health care from prominent psychiatrists.

EMP (EMPATHIC) COMMUNICATIONS
for the patient's family

The first in a series of booklets that answers a number of worrisome questions on how to cope with schizophrenia.

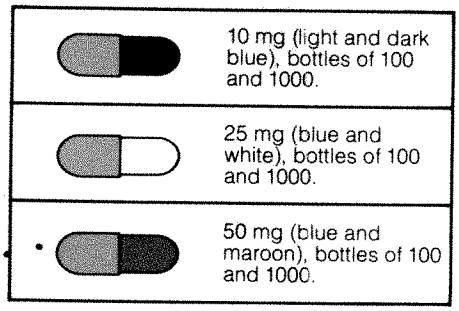
Other booklets offer specific information for *individual* members of the family and others in close contact with the patient, such as the employer, co-workers, paramedical personnel.

now...more than symptomatic control for the schizophrenic

EMP COMMUNICATIONS—an impressive educational program

PSYCHIATRIC INTERFACES—an outstanding information service

and



Daxolin™
(loxapine succinate)

a promising neuroleptic agent for symptomatic control of schizophrenia

See next page for prescribing information.

Daxolin™ (loxapine succinate)

individualized dosage strengths to meet the varying needs of the schizophrenic

10 mg (light and dark blue), bottles of 100 and 1000.

25 mg (blue and white), bottles of 100 and 1000.

50 mg (blue and maroon), bottles of 100 and 1000.

Description: DAXOLIN (loxapine succinate), a dibenzoxazepine compound, represents a new subclass of tricyclic antipsychotic agent, chemically distinct from the thioxanthenes, butyrophenones, and phenothiazines. Chemically, it is 2-chloro-11-(4-methyl-1-piperazinyl) dibenz[b,f][1,4] oxazepine. It is present in capsules as the succinate salt. Each 1.36 mg of loxapine succinate is equivalent to 1 mg of loxapine.

Actions: Pharmacologically, loxapine is a tranquilizer for which the exact mode of action has not been established. However, changes in the level of excitability of subcortical inhibitory areas have been observed in several animal species in association with such manifestations of tranquilization as calming effects and suppression of aggressive behavior.

In normal human volunteers, signs of sedation were seen within 20 to 30 minutes after administration, were most pronounced within 1½ to 3 hours, and lasted through 12 hours. Similar onset and duration of primary pharmacologic effect was seen in animals.

Absorption of loxapine following oral or parenteral administration is virtually complete. The drug is removed rapidly from the plasma and distributed in tissues. Animal studies suggest an initial preferential distribution in lungs, brain, spleen, heart, and kidney. Loxapine is metabolized extensively and excreted mainly in the first 24 hours. Metabolites are excreted in the urine in the form of conjugates but are unconjugated in the feces.

Indications: DAXOLIN is indicated for the manifestations of schizophrenia.

Contraindications: DAXOLIN (loxapine succinate) is contraindicated in comatose or severe drug-induced depressed states (alcohol, barbiturates, narcotics, etc.).

DAXOLIN is contraindicated in individuals with known hypersensitivity to the drug.

Warnings: *Usage in Pregnancy:* Safe use of DAXOLIN during pregnancy or lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the benefits of treatment be weighed against the possible risks to mother and child. No embryotoxicity or teratogenicity was observed in studies in rats, rabbits or dogs. With the exception of one rabbit study, the highest dosage was two times the maximum recommended human dose and in some studies the dose was lower. Perinatal studies have shown renal papillary abnormalities in offspring of rats treated from mid-pregnancy with doses of 0.6 and 1.8 mg/kg doses which approximate the usual human dose but which are considerably below the maximum recommended human dose.

Usage in Children: Studies have not been performed in children; therefore this drug is not recommended for use in children below the age of 16.

DAXOLIN, like other tranquilizers, may impair mental and/or physical abilities, especially during the first few days of therapy. Therefore, ambulatory patients should be warned about activities requiring alertness (eg, operating vehicles or machinery), and about concomitant use of alcohol and other CNS depressants.

Precautions: DAXOLIN should be used with extreme caution in patients with a history of convulsive disorders since it lowers the convulsive threshold. Seizures have been reported in epileptic patients receiving DAXOLIN at antipsychotic dose levels, and may occur even with maintenance of routine anticonvulsant drug therapy.

Loxapine has an antiemetic effect in animals. Since this effect also may occur in man, loxapine may mask signs of overdosage of toxic drugs and obscure conditions such as intestinal obstruction and brain tumor.

DAXOLIN should be used with caution in patients with cardiovascular disease. Increased pulse rates have been reported in the majority of patients receiving antipsychotic doses; and transient hypotension has been reported. In the presence of severe hypotension requiring vasopressor therapy, the preferred drugs may be norepinephrine or angiotensin. Usual doses of epinephrine may be ineffective because of inhibition of its vasopressor effect by loxapine.

The possibility of ocular toxicity from loxapine cannot be excluded at this time. Therefore, careful observation should be made for pigmentary retinopathy and lenticular pigmentation since these have been observed in some patients receiving certain other antipsychotic drugs for prolonged periods.

Because of possible anticholinergic action, the drug should be used cautiously in patients with glaucoma or a tendency to urinary retention, particularly with concomitant administration of anticholinergic-type antiparkinsonian medication.

Adverse Reactions: *CNS Effects:* Manifestations of adverse effects on the central nervous system, other than extrapyramidal effects, have been seen infrequently. Drowsiness, usually mild, may occur at the beginning of therapy or when dosage is increased. It usually subsides with continued DAXOLIN (loxapine succinate) therapy. The incidence of sedation has been less than that of certain aliphatic phenothiazines and slightly more than the piperazine phenothiazines. Dizziness, faintness, staggering gait, muscle twitching, weakness, and confusional states have been reported.

Extrapyramical Reactions—Neuromuscular (extrapyramidal) reactions during the administration of DAXOLIN have been reported frequently, often during the first few days of treatment. In most patients, these reactions involved parkinsonism-like symptoms such as tremor, rigidity, excessive salivation, and masked facies. Akathisia (motor restlessness) also has been reported relatively frequently. These symptoms are usually not severe and can be controlled by reduction of DAXOLIN dosage or by administration of antiparkinsonian drugs in usual dosage. Dystonic and dyskinetic reactions have occurred less frequently, but may be more severe. Dystonias include spasms of muscles of the neck and face, tongue protrusion, and oculogyric movement. Dyskinetic reaction has been described in the form of choreoathetoid movements. These reactions sometimes require reduction or temporary withdrawal of DAXOLIN dosage in addition to appropriate counteractive drugs.

Persistent Tardive Dyskinesia—In keeping with the action of all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients—especially females—on high-dose therapy. The symptoms are persistent and, in some patients, appear to be irreversible. The syndrome is characterized by rhythmical involuntary movement of the tongue, face, mouth, or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of the extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinsonian agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome; if the medication is stopped at that time the syndrome may not develop.

Cardiovascular Effects: Tachycardia, hypotension, hypertension, light-headedness, and syncope have been reported. A few cases of ECG changes similar to those seen with phenothiazines have been reported. It is not known whether these were related to loxapine administration.

Skin Effects: Dermatitis, edema (puffiness of face), pruritus, and seborrhea have been reported with loxapi The possibility of photosensitivity and/or phototoxi occurring has not been excluded; skin rashes of unc tain etiology have been observed in a few patients dur hot summer months.

Endocrine Effects: No endocrine abnormalities ha been reported.

Anticholinergic Effects: Dry mouth, nasal congesti constipation, and blurred vision have occurred; these more likely to occur with concomitant use of antiparkin nian agents.

Other Adverse Reactions: Nausea, vomiting, wei gain, weight loss, dyspnea, ptosis, hyperpyrexia, flush facies, headache, paresthesia, and polydipsia ha been reported in some patients.

Dosage and Administration: DAXOLIN (loxapine suc nate) is administered orally, usually in divided doses, t to four times a day. Daily dosage (in terms of base equ alents) should be adjusted to the individual patier needs as assessed by the severity of symptoms and p vious history of response to antipsychotic drugs. Init dosage of 10 mg twice daily is recommended althoug in severely disturbed patients, initial dosage up to a to of 50 mg daily may be desirable. Dosage should then b increased fairly rapidly over the first seven to ten da until there is effective control of psychotic symptoms. T usual therapeutic and maintenance range is 60 mg to 1 mg daily. However, as with other antipsychotic drug some patients respond to lower dosage and others r quire higher dosage for optimal benefit. Daily dosag higher than 250 mg is not recommended. For maint nance therapy, dosage should be reduced to the lowe level compatible with symptom control; many patier have been maintained satisfactorily at dosages in t range of 20 mg to 60 mg daily.

How Supplied: DAXOLIN™ (loxapine succinate) is su plied in the following base-equivalent strengths:

CAPSULES Hard Shell Printed "DOME"

10 mg—Light and Dark Blue; bottles of 100 and 1000

25 mg—Blue and White; bottles of 100 and 1000.

50 mg—Blue and Maroon; bottles of 100 and 1000.

DOM-1534

For the patient who needs a UNIQUE CONCEPT in MEDICAL and HOSPITAL CARE.

Las Encinas Hospital

Under complete supervision and direction of its Medical Staff, Las Encinas Hospital offers evaluation and treatment of a patient's total individual needs . . . psychological and physical.

A full time staff of Board certified specialists in Psychiatry, Internal Medicine, Radiology and Psychology, backed by a fully equipped and accredited hospital facility, offers clinical study, diagnosis, and long or short term care. All in a decidedly unhospital-like atmosphere of restful beauty, comfort, privacy and security. Rooms, suites and cottage accommodations available.

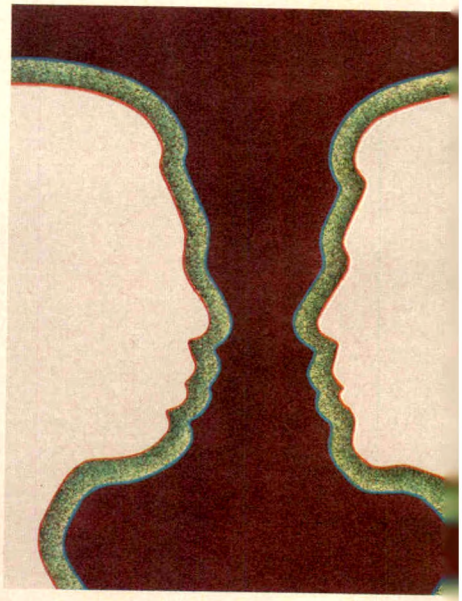
The American Journal of Psychiatry

will feature

- **Overview: Research on the Psychology of Women. II. Women in Families, Work, and Psychotherapy by Anne M. Seiden**



In treating the schizophrenic, there's something different about

MOBAN®
(molindone HCl)

acts on the RAS with low incidence of adverse effects

EEG studies show that MOBAN® exerts its effect on the ascending reticular activating system. This often helps to encourage increased social participation, receptivity and communication in schizophrenic patients.

Artist's representation of the reticular activating system, with neuronal activity passing on to cortical and subcortical structures.

- generally minimizes drowsiness to help produce improved functioning
  1) to hasten the discharge of hospitalized patients
  2) to keep ambulatory patients at home or on the job

- tranquilizes without muscle relaxant or incoordinating effect

- acts to alleviate target symptoms or reduce their severity
  1) in acute patients, some symptomatic improvement evident in a few days
  2) in chronic patients, symptomatic improvement may not be evident until 2-4 weeks
  3) maximum benefits attained by end of third month (continued maintenance therapy as required)

SOCIAL ADJUSTMENT PROFILE CHART

of 66 hospitalized schizophrenic patients treated with MOBAN® (molindone HCl) for 1 year or more*

Adjustment	Percent
To live on open ward	91%
To function with privileges	89%
To hold hospital job	85%
To leave hospital	70%
To maintain home	33%
To hold employment	32%

*Data on file, Endo Laboratories

How to use MOBAN® (molindone HCl)

a wide range of dosage strengths available in **Tablets:**

- Titrate for 1) therapeutic response and 2) minimal effective maintenance dose.
- Use lower doses for the elderly and debilitated.

NOTE: Transient drowsiness may occur during the first 1-2 weeks.

Whenever your schizophrenic patient may benefit from less sedation

MOBAN®

MOBAN® (molindone HCl)

a dihydroindolone chemically distinct from phenothiazines, thioxanthenes, butyrophenones

DESCRIPTION MOBAN® (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

MOBAN® is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4 (5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

MOLINDONE HYDROCHLORIDE

ACTIONS MOBAN® (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditional response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, MOBAN® antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, MOBAN® exerts its effect on the ascending reticular activating system.

Human metabolic studies show MOBAN® (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24-36 hours. There are 36 recognized metabolites with less than 2-3% unmetabolized MOBAN® being excreted in urine and feces.

INDICATIONS MOBAN® (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS MOBAN® (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS Usage in Pregnancy: Studies in the pregnant patient have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats oral dose—	
no adverse effect	20 mg/kg/day—2 weeks
no adverse effect	40 mg/kg/day—2 weeks
Pregnant Mice oral dose—	
slight increase resorptions	20 mg/kg/day—9 days
slight increase resorptions	40 mg/kg/day—9 days
Pregnant Rabbits oral dose—	
no adverse effect	5 mg/kg/day—12 days
no adverse effect	10 mg/kg/day—12 days
no adverse effect	20 mg/kg/day—12 days

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of MOBAN® (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of MOBAN® (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

PRECAUTIONS Some patients receiving MOBAN® (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving MOBAN®. Caution should be exercised where increased activity may be harmful.

MOBAN® does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, convulsive seizures have been reported in a few instances.

The physician should be aware that this tablet preparation contains calcium sulfate as an excipient and that calcium ions may interfere with the absorption of preparations containing phenytoin sodium and tetracyclines.

MOBAN® has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS CNS EFFECTS The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological

Extrapyramidal Reactions

Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia

Motor restlessness may occur early.

Parkinson Syndrome

Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome

Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System

Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological

There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with MOBAN® may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects

Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Lactation associated with MOBAN® therapy has not been reported. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with MOBAN®.

Cardiovascular

Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological

Lens opacities and pigmentary retinopathy have not been reported where patients have received MOBAN® (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with MOBAN®.

Skin

Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with MOBAN® usage alone.

MOBAN® (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when MOBAN® is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia

Although not reported with MOBAN® (molindone hydrochloride) late appearing dyskinesias have been associated with certain antipsychotic agents.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION Initial and maintenance doses of MOBAN® (molindone hydrochloride) should be individualized, and the minimal effective dose should be employed. Elderly and debilitated patients should be started on lower dosage.

DOSAGE SCHEDULE, BASED ON SEVERITY OF SYMPTOMATOLOGY

1. Mild—5 mg three or four times a day; an increase to 15 mg three or four times a day may be required.
2. Moderate—10 mg three or four times a day; an increase to 25 mg three or four times a day may be required.
3. Severe—daily dosage as high as 225 mg may be required.

DRUG INTERACTIONS Potentiation of drugs administered concurrently with MOBAN® (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when MOBAN® is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of MOBAN® (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of MOBAN® (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by MOBAN® in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized MOBAN® from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of MOBAN® is excreted unmetabolized in the urine.)

However, poor response of the patient may justify use of these procedures. While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized MOBAN® in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED As tablets in bottles of 100 and 1000 with potencies and colors as follows: 5 mg orange, 10 mg lavender, 25 mg light green.

*Benadryl—Trademark, Parke Davis and Co.
*Artane—Trademark, Lederle Laboratories
*Cogentin—Trademark, Merck Sharp & Dohme
*Akineton—Trademark, Knoll Pharmaceutical Co.

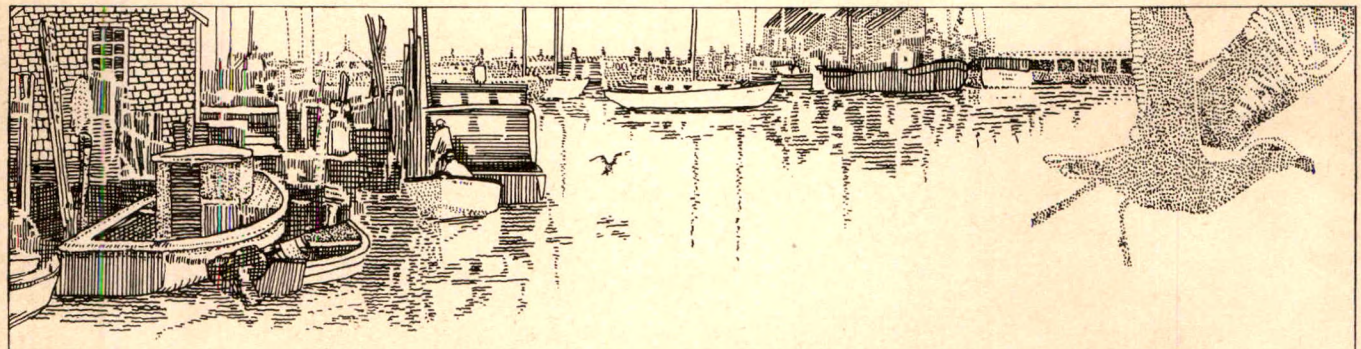
When a period of intensive residential treatment is indicated: THE BROWN SCHOOLS

A community within a community to provide individualized treatment within a residential milieu.

A program designed for: psychiatric illness, behavior problems in neurological patients, and rehabilitation of the mentally retarded.



Three separate treatment centers plus a transitional treatment center provide individually prescribed programs of care, education, treatment and training for children, adolescents and adults. The centers are geographically separated to provide the proper residential group, yet near enough to benefit from the combined training and experience of a wide range of staff members.

For information, write: The Director of Admissions, Department C-0, THE BROWN SCHOOLS, P.O. Box 4008, Austin, Texas 78765

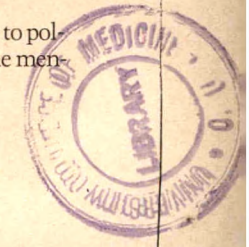
THE BROWN SCHOOLS

People and Predicaments

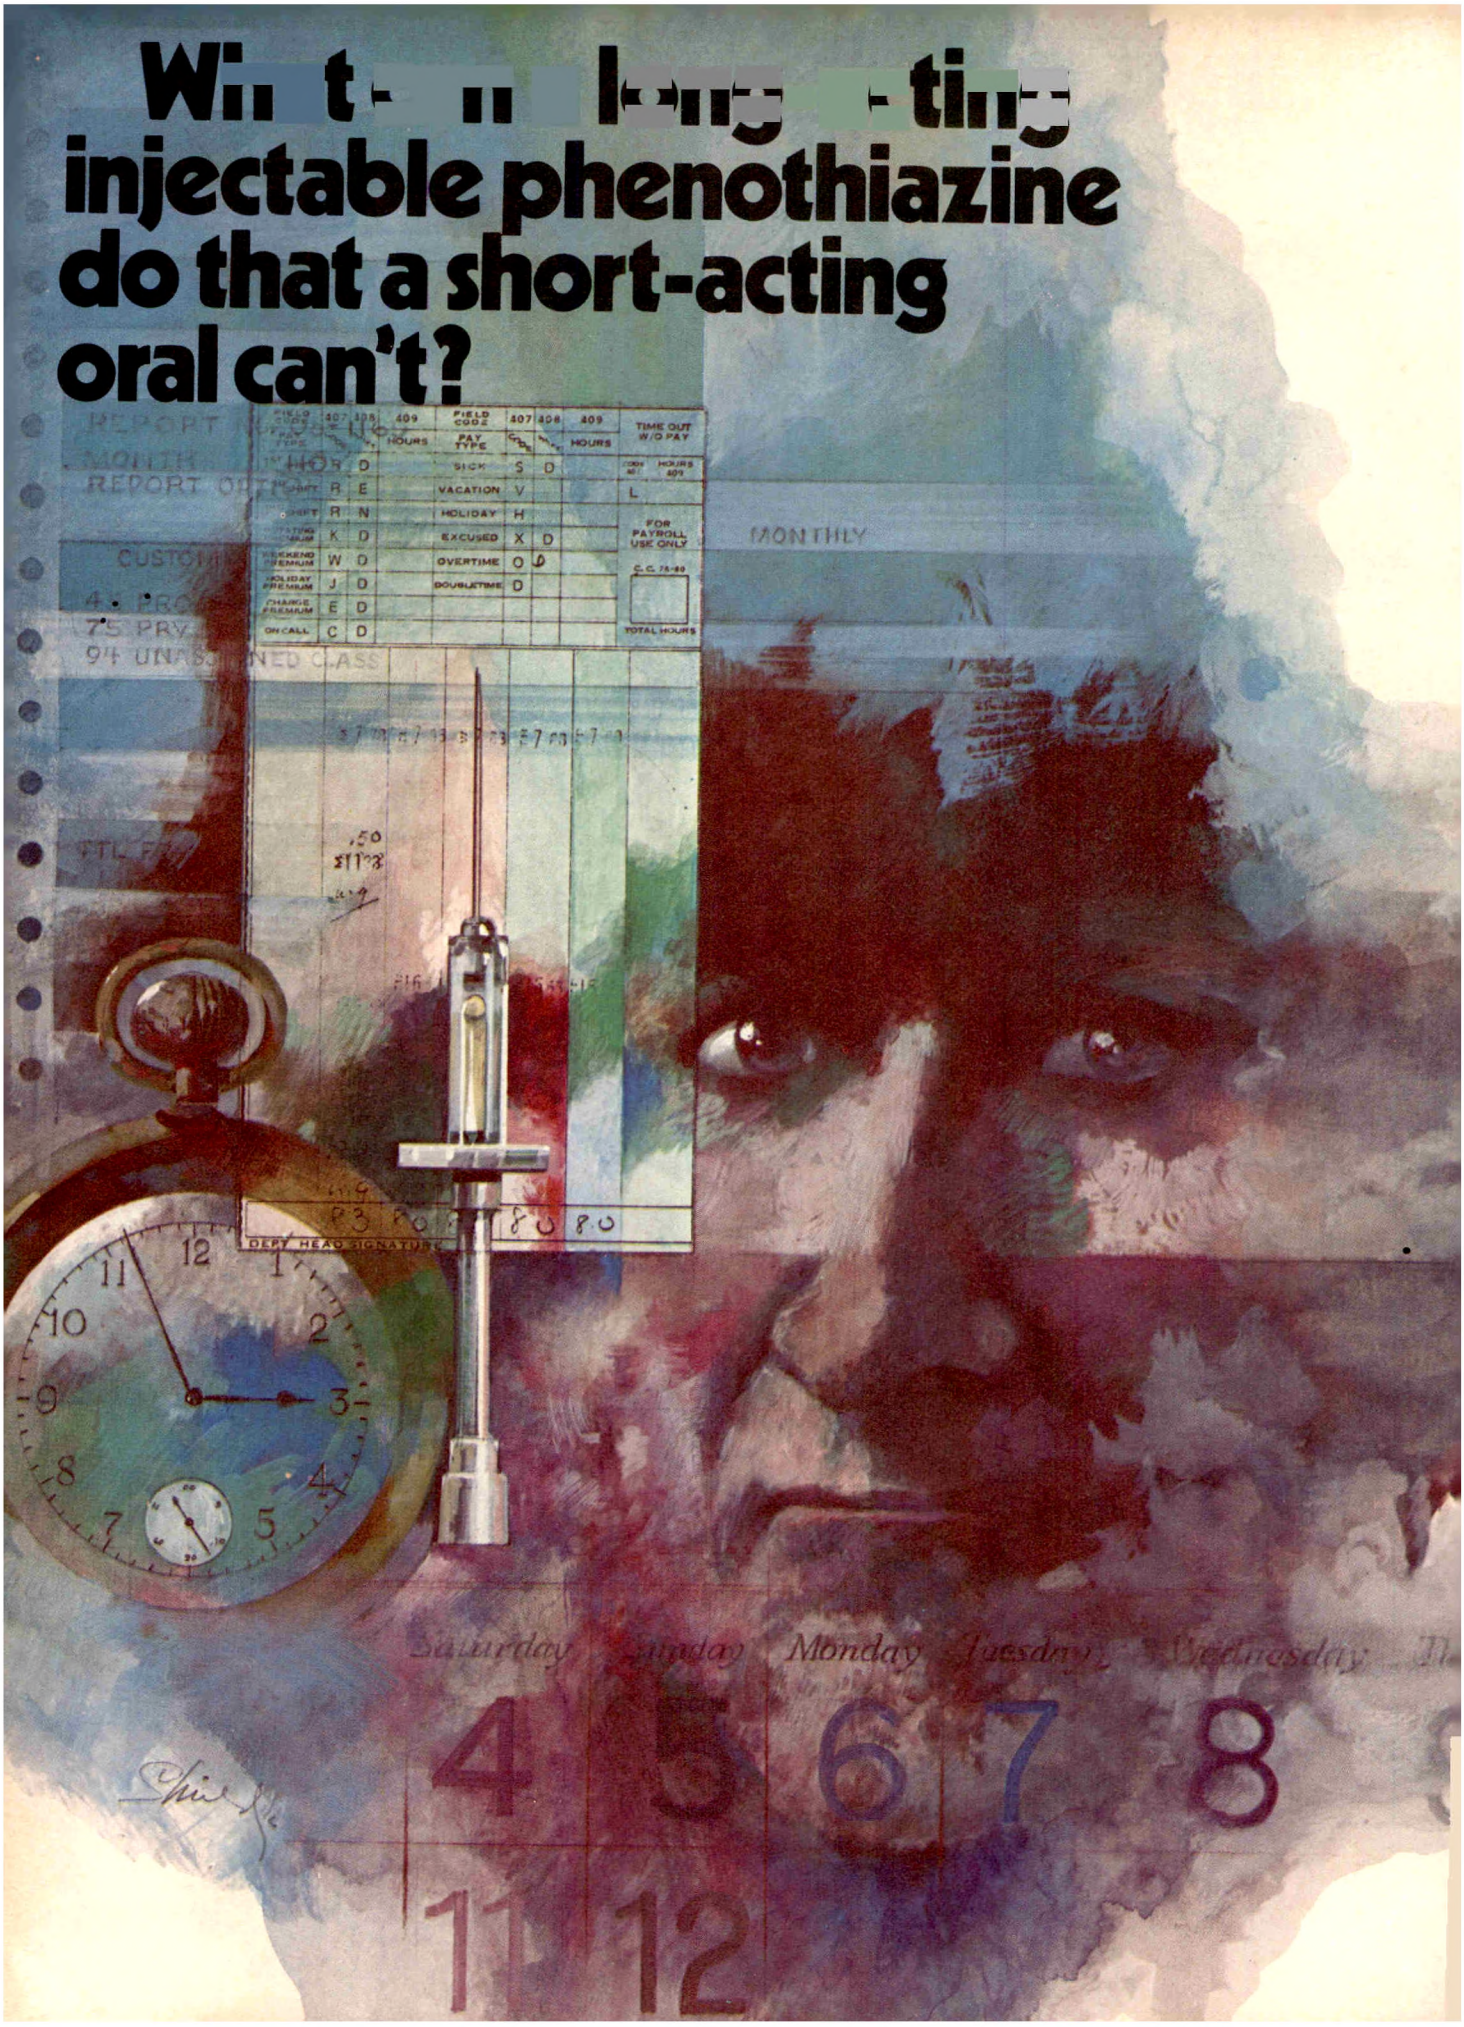
Of Life and Distress on Martha's Vineyard

Milton Mazer



This is the compelling story of an experiment begun in 1961 that eventually affected the lives of almost all of the residents of the island of Martha's Vineyard. The author writes engagingly of the island and its year-round inhabitants, a community of some seven thousand persons of diverse ethnic and social backgrounds.

With sympathy and insight Milton Mazer analyzes the stresses that are peculiar to the conditions of life on the island, and he describes the kinds of psychological disorders that are precipitated by those stresses. He reports, without technical jargon, the results of a five-year study of a great variety of psychosocial predicaments experienced by the people of the island. Finally he examines the catalytic effect the mental health center and its research findings have had on the development of other supportive agencies and how the community established a network of human services to meet its needs.



"It is an important book and should be of interest to policy makers, planners, and program developers in the mental health field." — Alexander Leighton, M.D.

Wi[illegible] injectable phenothiazine do that a short-acting oral can't?

It can save time

Prolixin Decanoate (Fluphenazine Decanoate Injection), with duration of action that may last up to 4 weeks or longer in patients on maintenance therapy, can effect important savings in nursing time.

Approximate Staff Time Required to Medicate 18 Schizophrenic Patients*

	
8 a.m. ¾ hr. 1 p.m. ¾ hr. 6 p.m. ¾ hr.	1 injection every 28 days for most patients
= 2¼ hours nursing time	4 minutes required for each injection
2¼ hrs. x 28 days = 63 hours of nursing time every 28 days	= 1 hr., 10 minutes nursing time in 28 days
NURSING TIME SAVED IN 28 DAYS	61 hours and 50 minutes or more than 7½ eight-hour working days

*Adapted from Platt R: Br J Social Psychiatry 2: 187-191, 1968.

It can save money

Martin and Townend[1], who found from their study of Prolixin Decanoate that 15 of 39 patients could be maintained on 25 mg. every 4 weeks, also note that on this basis "a year's maintenance on chlorpromazine represents the order of 110 grams of phenothiazine as opposed to 0.33 gram of fluphenazine." Translating this into dollars shows the following potential hospital savings on the basis of patient population:

Agent and amount/year	Form	Cost/patient/ year	Cost/500 patients/ year
Chlorpromazine (SKF brand) 110 grams	8 oz. concentrate 100 mg./ml.†	$48.75*	$24,375
Prolixin Decanoate .33 grams	5 ml. vials 25 mg./ml.	$26.08**	$13,040
SAVINGS		$22.67 patient, year	$11,335 500 pts/yr.

* Calculated from prices published in 1976 Red Book.
** Calculated from Squibb 1976 price catalogue.
† With tablets, the annual cost is even greater.

It can even save people– by reducing readmissions

The controlled drug delivery system of Prolixin Decanoate helps get schizophrenic patients out of the hospital and helps them stay out. It promotes continuity of therapy—reducing outpatient drug defaulting from approximately 50% with oral medications according to one report[2] to about 16% according to another report[3].

It reduces the number and length of rehospitalizations. In one study of 103 patients maintained on injections of long-acting fluphenazines, total hospital readmissions for a year were cut from 191 to 50 and inpatient time from 8,713 days to 1,335 days[4].

It facilitates return to a productive life. A 12-month followup of 103 discharged patients revealed 77% in full-time employment or household duties and only 23% unemployed[4].

SQUIBB®

Prolixin Decanoate®
Fluphenazine Decanoate Injection

may control schizophrenic symptoms for up to 4 weeks or longer in patients on maintenance therapy.

See next page for brief summary of prescribing information.

rolixin Dec noate®

Fluphenazine Decanoate Injection

may control schizophrenic symptoms for up to 4 weeks or longer in patients on maintenance therapy.

Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per ml. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia or liver damage, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety and efficacy in children have not been established because of inadequate experience in use in children.

Usage in Pregnancy: Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administering this drug to pregnant patients.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anticholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with a history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of antiparkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, persistent and sometimes irreversible tardive dyskinesia may appear in some patients on long-term therapy or may occur after discontinuation of drug. The risk seems greater in elderly patients, especially females, on high dosages. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and may be accompanied by involuntary movements of extremities. There is no known effective therapy for tardive dyskinesia; usually the symptoms are not alleviated by antiparkinsonism agents. If the symptoms appear, discontinuation of all antipsychotic agents is suggested. The syndrome may be masked if treatment is reinstituted, or drug dosage increased, or a different antipsychotic agent used. Reports are that fine vermicular movements of the tongue may be an early sign of the syndrome which may not develop if medication is stopped at that time.

Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams; reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia, or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Systemic lupus erythematosus-like syndrome, hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

HOW SUPPLIED: 1 ml. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 ml. vials.

in clinically significant depression...

penetrating the symptom barrier to productive psychotherapy

symptoms often interfere with therapy

In clinically significant depression, the patient often becomes barricaded behind his own symptoms during psychotherapy. Because these symptoms can be so sharply defined and somatic in expression, he may reject the fact that they are psychic in origin. Sleep disturbance, gastrointestinal complaints, anorexia, chronic fatigue, and other psychosomatic symptoms may so preoccupy—or overwhelm—the depressed patient that truly productive therapeutic sessions are difficult to achieve. Instead of being able to concentrate on the core emotional problems of the depression itself, he may for example go on at length about how broken his sleep is or keep reiterating (while the therapeutic hour slips by) how physically miserable he feels.

ELAVIL®
(AMITRIPTYLINE HCl, MSD)
to help penetrate the symptom barrier in depression requiring medication

ELAVIL, a highly effective tricyclic antidepressant, will often alleviate these symptoms. With the help of ELAVIL, sleep disturbance—so common in clinically depressed patients and often the symptom that distresses them most—as

well as other "barrier symptoms" may be lessened to the point where they no longer come between you and the patient.

psychotherapy takes direction

As these preoccupying complaints are lifted, psychotherapy sessions can become more productive. Patients are enabled to respond more fruitfully during therapeutic hours and to resume or pursue more efficiently the necessary activities in their personal lives.

meeting therapeutic goals

And as the antidepressant activity of ELAVIL (Amitriptyline HCl, MSD) takes hold, it helps relieve the depressive condition itself. Sometimes only a minimum of actual psychotherapy is required. The patient may experience a more rapid recovery—while you conserve valuable time.

Prescribe ELAVIL then, to help lighten the patient's burden in depression—and yours in its management.

ELAVIL should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Its safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

TABLETS: 10 mg, 25 mg, 50 mg, 75 mg, and 100 mg
INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

an antidepressant with an anxiety-reducing sedative component to its action

MSD
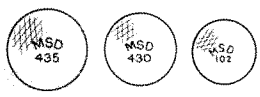
MERCK
SHARP &
DOHME

addendum

ELAVIL®



(AMITRIPTYLINE HCl | MSD)

Five tablet strengths for differing patient needs. The variety of dosage strengths available with ELAVIL makes possible great prescribing flexibility.

Once-a-day dosage at bedtime is an appropriate way to start—and maintain—many patients on therapy. The simplicity of this regimen helps improve patient compliance. ELAVIL may also be prescribed in divided daily doses.

A sedative effect may be apparent before the antidepressant effect of ELAVIL is noted. An adequate therapeutic effect may take as long as 30 days to develop.

100 mg
75 mg
50 mg

These tablets may be advantageous when initiating therapy with once-daily bedtime dosage in adult outpatients. The usual starting dosage is 75 mg daily. Therapy may be initiated with 50 to 100 mg daily. This may be increased by 25 or 50 mg as necessary in the bedtime dose to a total of 150 mg per day.

These tablets may also be convenient for many hospitalized patients. These patients may need 100 mg a day initially which can be increased gradually to 200 mg a day if necessary. A small number of such patients may need as much as 300 mg a day.

25 mg 

This tablet may prove useful when initiating therapy with divided daily doses in adult outpatients. Starting dosage is usually 75 mg daily. If necessary, this dosage may be increased gradually to a total of 150 mg a day. Increases are made preferably in the late afternoon or bedtime doses.

10 mg 

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher doses.

NOTE: The usual maintenance dosage of ELAVIL is 50 to 100 mg per day which may be given in a single dose preferably at bedtime. In some patients 40 mg per day is sufficient. This drug is not recommended for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required; paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported. Use with caution in patients with impaired liver function.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue, rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; tablets containing 75 mg and 100 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

The third annual

TEMPLE CONFERENCE ON BEHAVIOR THERAPY AND BEHAVIOR MODIFICATION

October 7-10, 1976
at the Hilton Hotel of Phila.

Lectures and workshops at introductory and advanced levels will emphasize practical application. Sponsored by the Department of Psychiatry, Temple University Medical School and Eastern Pennsylvania Psychiatric Institute.

Lecturers and workshop leaders:
Paula Bram Amar, L. Michael Ascher, Teodoro Ayllon, Nathan H. Azrin, Albert Bandura, John Paul Brady, Joseph R. Cautela, Alberto DiMascio, Steven C. Fischer, Edna B. Foa, Iris G. Fodor, W. Horsley Gantt, Louis Gershman, Michael Goldblatt, Martin Gittelman, Israel Goldiamond, Alan Goldstein, Gerald Groves, Michel Hersen, Leonard Krasner, Donald J. Levis, Michael J. Mahoney, David I. Mostofsky, Anthony F. Panzetta, Debora Phillips, Leo J. Reyna, Morton Rubin, Barry Shmavonian, Richard B. Stuart, Johann Stoyva, Joseph Wolpe

Symposium: Psychotherapeutic Change: Conditioning or Cognitive Process?

FEES: $45 for General Registration ($50 after September 30th), which includes all lectures and films. There will be an additional fee for workshops and conversation hours. The workshops will be limited to 25 participants.

For a copy of the program, please write: Dr. Edna B. Foa, Behavior Therapy Unit, Room 702, c/o E.P.P.I., Henry Ave., Phila., PA 19129 (215) 438-4298, x.54.

Announcing

FIRST INTERNATIONAL SYMPOSIUM

on
Immunological Components in Schizophrenia

Sponsored by
The National Foundation – March of Dimes

To be held at
The University of Texas Medical Branch
Galveston, Texas

October 28-31, 1976

This symposium will draw together investigators in immunology, virology, biochemistry, pharmacology, genetics, endocrinology and psychiatry for a critical inquiry of the possible role of the immune system in the development of schizophrenia.

The program will consist of invited presentations and discussion among symposium participants with proceedings to be published by The National Foundation in "Birth Defects: Original Article Series."

For further information, contact:
Coordinator
Multidisciplinary Research Program in Mental Health
Room 626, Basic Science Building
The University of Texas Medical Branch
Galveston, Texas 77550

MOSBY
TIMES MIRROR

KEEP PACE
with the latest innovations in psychiatric care. . .

New Mosby books explore the nature of psychopathy. . .

New 5th Edition!

MASK OF SANITY

Retaining the excellent clinical orientation and readability of earlier editions, this new edition has been thoroughly updated to include important new findings, new references, and examples of the psychopathic personality. Renowned psychiatrist, Dr. Hervey Cleckley, presents a series of case studies that vividly illustrates the reality behind the "mask of sanity" worn by sociopaths.

By Hervey Cleckley, M.D. March, 1976. 5th edition, 472 pages plus FM I-XVI, 6½" x 9½". Price, $14.95.

the earliest relationship of mother and child. . .

A New Book!

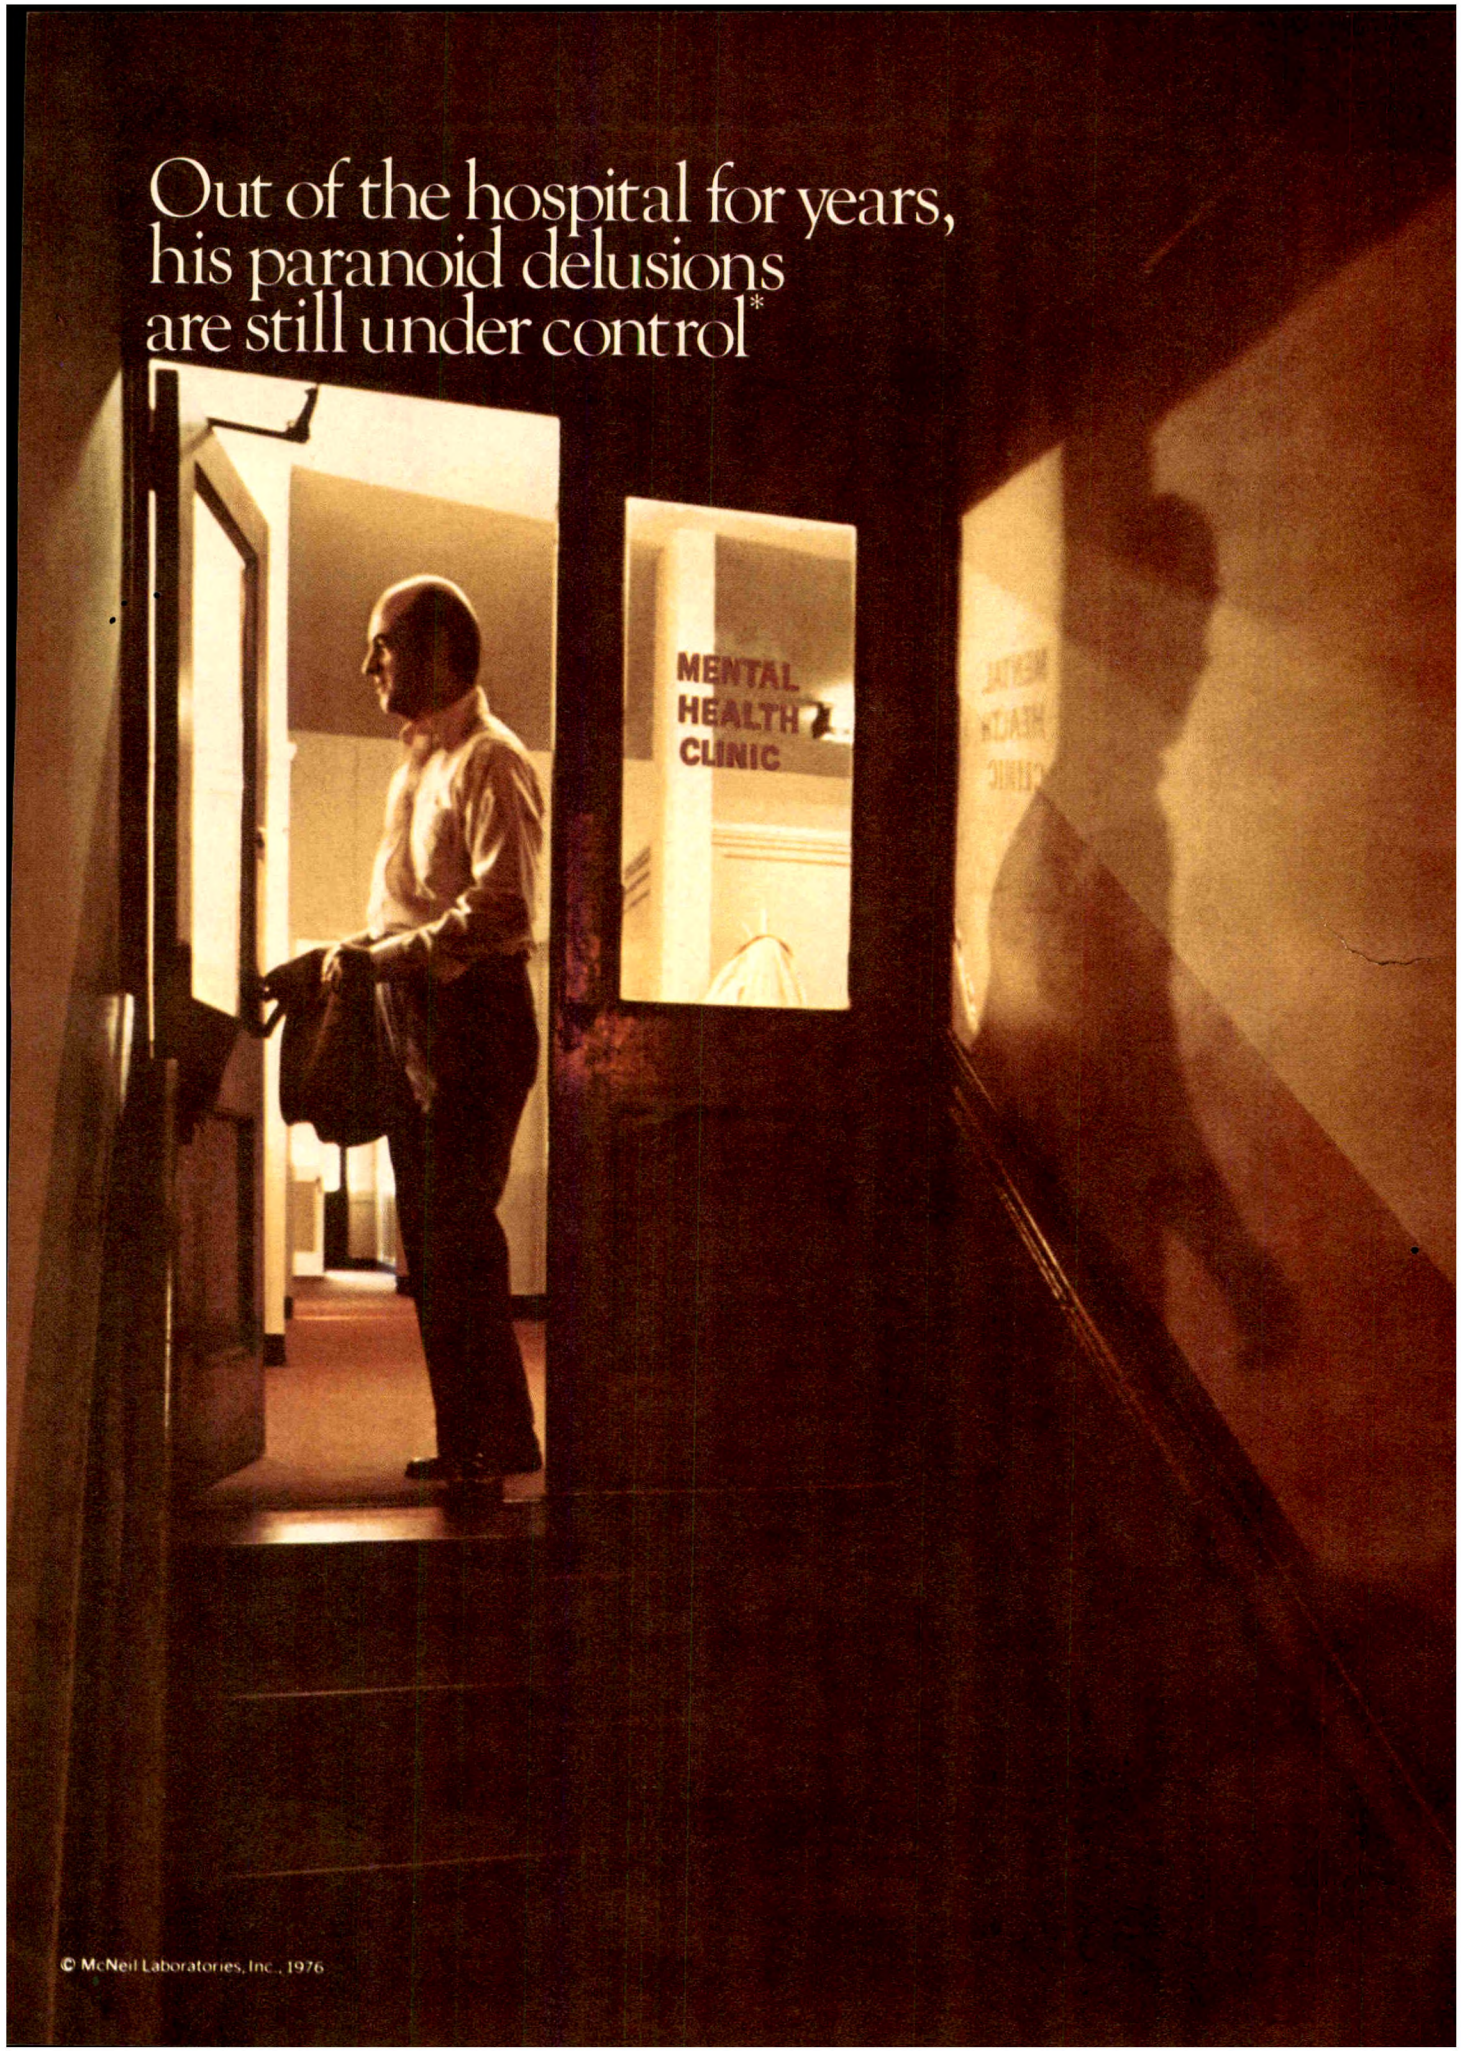
MATERNAL-INFANT BONDING: The Impact of Early Separation or Loss on Family Development

The authors of this new book stress that the time immediately after birth is critical for both newborn and parents: initial interaction may have a profound effect on family development. The book examines factors that enhance or inhibit this earliest relationship and offers new approaches to care of the newborn and family. Discussions include commentary by psychiatrists and pediatricians; interviews with parents; statistics; and more.

By Marshall H. Klaus, M.D. and John H. Kennell, M.D. August, 1976. 258 pages plus FM I-XVIII, 6" x 9", 49 illustrations. About $8.95 (C); about $6.25 (P).

the standardization of psychiatric care. . .

A New Book!



THE PROBLEM-ORIENTED PSYCHIATRIC INDEX AND TREATMENT PLANS

This new book is the first to demonstrate the standardization of psychiatric treatment through the Problem-Oriented Psychiatric Index. It presents a comprehensive method for scientifically formulating goals and treatment plans.

By Monte J. Meldman, M.D.; Gertrude McFarland, R.N., M.S.; and Edith Johnson, B.A. July, 1976. 202 pages plus FM I-X, 8" x 10", 88 illustrations. Price, $7.50.

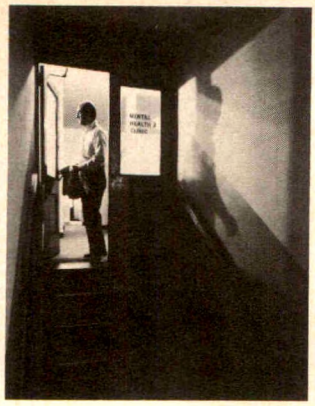
Haldol®
(haloperidol)
tablets/concentrate/injection

For long-term control with minimal risk of toxicity

Highly effective in a wide range of psychotic symptoms,[1-7]
such as hallucinations, delusions, suspiciousness, hostility, mania, psychomotor agitation, etc., in both acute and chronic disorders.

Usually leaves patients relatively alert and responsive...[1-3]
better able to cope with job and family responsibilities...as well as easier to reach with supportive and rehabilitative measures.

Permits aggressive titration to effective dosage levels,[1,4]
up to 100 mg/day orally (with minimal risk of usual troublesome reactions) to achieve optimal response when patient is inadequately controlled at lower dosage...to help you rapidly control and stabilize new patients, promptly regain control during periods of exacerbation.



Common side effects easily controlled.[1,3-6]
Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Reduces risk of certain troublesome reactions.[2-5,7]
Transient hypotension occurs rarely and severe orthostatic hypotension has not been reported. Marked sedation is rare, although some instances of drowsiness have been reported. In addition, with chronic use, it is unlikely to cause hepatic damage, serious hematologic reactions, photosensitivity reactions and skin rashes...and has minimal effect on renal function.

Please turn page for information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions.

Important: Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

Haldol® (haloperidol)

tablets/concentrate/injection

For long-term control of psychotic symptoms with minimal risk of toxicity

A Dosage Form for Every Need:

5 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg., 5 mg. and 10 mg.

A tasteless, odorless, colorless liquid concentrate for better patient acceptability: 2 mg. per ml.

A rapid-acting injection for psychiatric emergencies: 5 mg. per ml., with 1.8 mg. methylparaben and 0.2 mg. propylparaben per ml., and lactic acid for pH adjustment to 3.4±0.2.

Indications: HALDOL haloperidol is indicated for use in the management of manifestations of psychotic disorders.

It is also indicated for the control of tics and vocal utterances of Gilles de la Tourette's syndrome.

Contraindications: HALDOL haloperidol is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy:*** Safe use of HALDOL haloperidol in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of haloperidol orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children: Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL haloperidol, decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL haloperidol may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL haloperidol should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL haloperidol may lower the convulsive threshold. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant antiparkinson medication is required, it may have to be continued after HALDOL haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson agents, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of antiparkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Persistent Tardive Dyskinesia*—Tardive dyskinesia may appear during long-term therapy or after therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. There is no known effective treatment. All antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL haloperidol is administered or prescribed. 9/74

Results of 11 controlled studies[1] evaluated by the Brief Psychiatric Rating Scale to determine the efficacy of LOXITANE® Loxapine Succinate by comparing it with trifluoperazine and chlorpromazine. They do not imply a claim of differential effectiveness or superiority. However, certain trends, not statistically significant, suggest superiority. These require further tests for confirmation.

Loxitane®
LOXAPINE SUCCINATE
Lederle

From the record:

LOXITANE has favorable trends

exhibited certain in side effects profile

While cardiac arrest, blood dyscrasias and renal toxicity have been reported with other antipsychotic agents, they have not been seen with LOXITANE. Hepatotoxicity manifested by jaundice or biliary stasis has not been observed. Transient liver enzyme changes, however, have been reported, but it has not been determined whether they are related to LOXITANE administration.

Although a few cases of changes in ECG have been reported, a causal relationship between this reaction and LOXITANE has not been established. Clinical experience with LOXITANE has not demonstrated ocular toxicity, however, the possibility of its occurrence cannot be ruled out at this time. Of the various endocrine abnormalities, only galactorrhea has been noted with LOXITANE, and only in rare instances.

Manifestations of adverse effects on the central nervous system other than extrapyramidal symptoms have been encountered infrequently, and drowsiness, when it occurs, is usually mild and subsides with continued therapy. Skin rashes of uncertain etiology have been observed in a few patients during the hot summer months; therefore the possibility of phototoxicity and/or photosensitivity cannot be excluded. Like certain other antipsychotic agents, LOXITANE lowers the convulsive threshold and should be used with extreme caution in patients with a history of convulsive disorders.

In general, LOXITANE presents a profile of extrapyramidal side effects similar to that of other agents used in the treatment of schizophrenia.

Cardiovascular effects such as hypotension, hypertension, light-headedness and syncope have been reported. Anticholinergic effects seen with LOXITANE include dry mouth, nasal congestion, constipation and blurred vision.

See LOXITANE prescribing information on next page for contraindications, warnings and precautions and for more detailed information concerning side effects.

A range of dosage strengths to suit the patient's individual needs

Supplied

Capsules

10 mg Green and Yellow

25 mg Green Two Tone

50 mg Green and Blue

Recommended Daily Dosage

Initial Dosage	MILD 10 mg b.i.d.	MODERATE 10 mg t.i.d. or q.i.d.	SEVERE 25 mg b.i.d.
First 7 to 10 Days	Increase dosage until psychotic symptoms are controlled. Dosage should not exceed 250 mg/day. Usual dosage during titration: 50 to 150 mg/day.		
Maintenance Dosage	Adjust to lowest effective level. Usual maintenance dosage: 60 to 100 mg/day. Many patients are controlled with dosages as low as 20 to 60 mg/day.		

Loxitane®
LOXAPINE SUCCINATE
Lederle

Because efficacy and side effects are a single consideration

Loxitane®
LOXAPINE Lederle SUCCINATE

Because efficacy and side effects are a single consideration

FOR ORAL USE

DESCRIPTION

LOXITANE *loxapine*, a dibenzoxazepine compound, represents a new subclass of tricyclic antipsychotic agent, chemically distinct from the thioxanthenes, butyrophenones, and phenothiazines. Chemically, it is 2-chloro-11-(4-methyl-1-piperazinyl)dibenz[b,f] [1,4]oxazepine. It is present in capsules as the succinate salt. Each 1.36 mg. of loxapine succinate is equivalent to 1 mg. of loxapine.

ACTIONS

Pharmacologically, loxapine is a tranquilizer for which the exact mode of action has not been established. However, changes in the level of excitability of subcortical inhibitory areas have been observed in several animal species in association with such manifestations of tranquilization as calming effects and suppression of aggressive behavior.

In normal human volunteers, signs of sedation were seen within 20 to 30 minutes after administration, were most pronounced within 1½ to 3 hours, and lasted through 12 hours. Similar timing of primary pharmacologic effects was seen in animals.

Absorption of loxapine following oral or parenteral administration is virtually complete. The drug is removed rapidly from the plasma and distributed in tissues. Animal studies suggest an initial preferential distribution in lungs, brain, spleen, heart, and kidney. Loxapine is metabolized extensively and is excreted mainly in the first 24 hours. Metabolites are excreted in the urine in the form of conjugates and in the feces unconjugated.

INDICATIONS

LOXITANE *loxapine succinate* is indicated for the manifestations of schizophrenia.

LOXITANE has not been evaluated for the management of behavioral complications in patients with mental retardation, and therefore it cannot be recommended.

CONTRAINDICATIONS

LOXITANE is contraindicated in comatose or severe drug-induced depressed states (alcohol, barbiturates, narcotics, etc.)

LOXITANE is contraindicated in individuals with known hypersensitivity to the drug.

WARNINGS

Usage in Pregnancy—Safe use of LOXITANE *loxapine succinate* during pregnancy or lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the benefits of treatment be weighed against the possible risks to mother and child. No embryotoxicity or teratology was observed in studies in rats, rabbits or dogs, although with the exception of one rabbit study, the highest dosage was only two times the maximum recommended human dose and in some studies they were below this dose. Perinatal studies have shown renal papillary abnormalities in offspring of rats treated from mid-pregnancy with doses of 0.6 and 1.8 mg/kg, doses which approximate the usual human dose but which are considerably below the maximum recommended human dose.

Usage in Children—Studies have not been performed in children; therefore this drug is not recommended for use in children below the age of 16.

LOXITANE, like other tranquilizers, may impair mental and/or physical abilities, especially during the first few days of therapy. Therefore, ambulatory patients should be warned about activities requiring alertness (eg, operating vehicles or machinery), and about concomitant use of alcohol and other CNS depressants.

PRECAUTIONS

LOXITANE should be used with extreme caution in patients with a history of convulsive disorders since it lowers the convulsive threshold. Seizures have been reported in epileptic patients receiving LOXITANE at antipsychotic dose levels, and may occur even with maintenance of routine anticonvulsant drug therapy.

Loxapine has an antiemetic effect in animals. Since this effect may also occur in man, loxapine may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

LOXITANE should be used with caution in patients with cardiovascular disease. Increased pulse rates have been reported in the majority of patients receiving antipsychotic doses; transient hypotension has been reported. In the presence of severe hypotension requiring vasopressor therapy, the preferred drugs may be norepinephrine or angiotensin. Usual doses of epinephrine may be ineffective because of inhibition of its vasopressor effect by loxapine.

The possibility of ocular toxicity from loxapine cannot be excluded at this time. Therefore, careful observation should be made for pigmentary retinopathy and lenticular pigmentation since these have been observed in some patients receiving certain other antipsychotic drugs for prolonged periods.

Because of possible anticholinergic action, the drug should be used cautiously in patients with glaucoma or a tendency to urinary retention, particularly with concomitant administration of anticholinergic-type antiparkinson medication.

ADVERSE REACTIONS

CNS Effects—Manifestations of adverse effects on the central nervous system, other than extrapyramidal effects, have been seen infrequently. Drowsiness, usually mild, may occur at the beginning of therapy or when dosage is increased.

It usually subsides with continued LOXITANE therapy. The incidence of sedation has been less than that of certain aliphatic phenothiazines and slightly more than the piperazine phenothiazines. Dizziness, faintness, staggering gait, muscle twitching, weakness, and confusional states have been reported.

Extrapyramidal Reactions—Neuromuscular (extrapyramidal) reactions during the administration of LOXITANE *loxapine succinate* have been reported frequently, often during the first few days of treatment. In most patients, these reactions involved Parkinson-like symptoms such as tremor, rigidity, excessive salivation, and masked facies. Akathisia (motor restlessness) also has been reported relatively frequently. These symptoms are usually not severe and can be controlled by reduction of LOXITANE dosage or by administration of antiparkinson drugs in usual dosage. Dystonic and dyskinetic reactions have occurred less frequently, but may be more severe. Dystonias include spasms of muscles of the neck and face, tongue protrusion, and oculogyric movement. Dyskinetic reaction has been described in the form of choreo-athetoid movements. These reactions sometimes require reduction or temporary withdrawal of LOXITANE dosage in addition to appropriate counteractive drugs.

Persistent Tardive Dyskinesia—As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movement of the tongue, face, mouth, or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinson agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Cardiovascular Effects—Tachycardia, hypotension, hypertension, lightheadedness, and syncope have been reported.

A few cases of ECG changes similar to those seen with phenothiazines have been reported. It is not known whether these were related to loxapine administration.

Skin—Dermatitis, edema (puffiness of face), pruritus, and seborrhea have been reported with loxapine. The possibility of photosensitivity and/or phototoxicity occurring has not been excluded; skin rashes of uncertain etiology have been observed in a few patients during hot summer months.

Anticholinergic Effects—Dry mouth, nasal congestion, constipation, and blurred vision have occurred; these are more likely to occur with concomitant use of antiparkinson agents.

Other Adverse Reactions—Nausea, vomiting, weight gain, weight loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, and polydipsia have been reported in some patients. Rarely, galactorrhea and menstrual irregularity of uncertain etiology have been reported.

DOSAGE AND ADMINISTRATION

LOXITANE *loxapine succinate* is administered orally usually in divided doses two to four times a day. Daily dosage (in terms of base equivalents) should be adjusted to the individual patient's needs as assessed by the severity of symptoms and previous history of response to antipsychotic drugs. Initial dosage of 10 mg twice daily is recommended, although in severely disturbed patients initial dosage up to a total of 50 mg daily may be desirable. Dosage should then be increased fairly rapidly over the first seven to ten days until there is effective control of psychotic symptoms. The usual therapeutic and maintenance range is 60 mg to 100 mg daily. However, as with other antipsychotic drugs, some patients respond to lower dosage and others require higher dosage for optimal benefit. Daily dosage higher than 250 mg is not recommended. For maintenance therapy, dosage should be reduced to the lowest level compatible with symptom control; many patients have been maintained satisfactorily at dosages in the range of 20 mg to 60 mg daily.

HOW SUPPLIED

LOXITANE *loxapine succinate* is supplied in the following base equivalent strengths:

CAPSULES Hard Shell Printed "Lederle"

10 mg—Green and Yellow; Bottles of 100, 1000, and unit dose 10 x 10's—Product Number 5360.

25 mg—Green Two Tone; Bottles of 100, 1000, and unit dose 10 x 10's—Product Number 5361.

50 mg—Green and Blue; Bottles of 100, 1000, and unit dose 10 x 10's—Product Number 5362.

UNIQUE-NESS:

In People & at the Lutheran Hospital Psychiatric Care Unit

Providing complete psychiatric care in a general hospital setting with special emphasis on disorders of adolescence.

Lutheran Hospital of Milwaukee, Inc.

Basil Jackson, M.D., D.P.M., M.Th., D.Sc., F.A.C.P.
Chairman, Department of Psychiatry
2200 W. Kilbourn Ave., Milwaukee, WI. 53233

THE AMERICAN JOURNAL OF PSYCHIATRY

NOW, your journals can become an attractive permanent part of your professional library. These famous Jesse Jones volume files, especially designed to keep your copies orderly, readily accessible for future reference—guard against soiling, tearing, wear or misplacement of copies. These durable files will support 150 lbs. Looks and feels like leather and is washable. The 23-carat gold lettering makes it a fit companion for the most costly binding.

Reasonably priced, too. Only $4.25, 3 for $12.00, 6 for $22.00 POSTPAID U. S. A. ORDERS ONLY. Satisfaction unconditionally guaranteed or your money back.

JESSE JONES BOX CORP. (Since 1843)
Department JP9—Philadelphia 41, Pa. 19141

A Psychiatric Glossary

Edited by a subcommittee of the AMERICAN PSYCHIATRIC ASSOCIATION Committee on Public Information.

The new Fourth Edition marks a striking expansion of definitions: 400 terms have been added and many of the terms appearing in earlier editions have received revised explanations. In addition to the GLOSSARY's continuing value to lawyers, teachers, journalists, social workers, and others, the new edition will be useful to medical students and first year residents in psychiatry.

Some major changes in the Fourth Edition:

- Expansion from 102 to 156 pages to accommodate 400 new terms
- New tables of terms in seven areas of contemporary concern
  - Drugs Used in Psychiatry
  - Legal Terms
  - Neurologic Deficits
  - Psychological Tests
  - Research Terms
  - Schools of Psychiatry
  - Sleep Disorders
- A comprehensive set of terms used in behavior therapy is included for the first time.

Paperback edition—$3.00 each, (See coupon for bulk discounts), may be ordered from the AMERICAN PSYCHIATRIC ASSOCIATION, Publications Sales, 1700 18th St. N.W., Washington, D.C. 20009.

Hardback edition—$7.95 may be ordered from Basic Books, Inc., 10 East 53rd Street, New York, New York 10022.

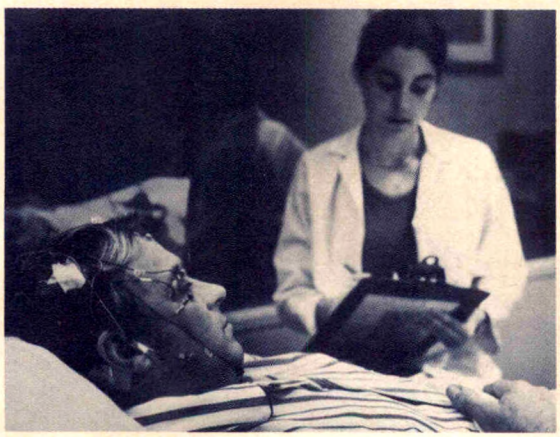
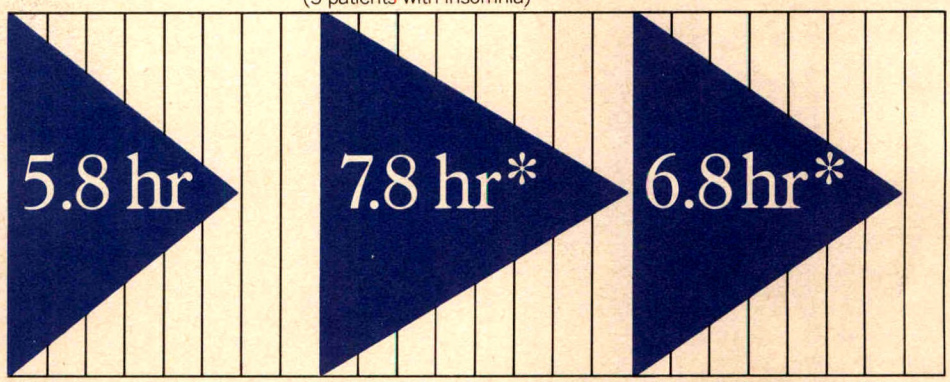
From the sleep research laboratory:



Dalmane® (flurazepam HCl) proved the most effective hypnotic over 14 nights...[1]

14 consecutive nights:
3 in sleep laboratory, 8 at home,
3 in sleep laboratory

...and now, the only one proved effective over 28 nights.[2,3]



28 consecutive nights:
3 in sleep laboratory, 7 at home,
4 in sleep laboratory, 10 at home,
4 in sleep laboratory[3]

For those patients who need it, Dalmane (flurazepam HCl) alone provides continued effectiveness[2,3]

Since insomnia is often transient and intermittent, the prolonged administration of a hypnotic is generally not necessary or recommended. But for those patients whose insomnia is a chronic problem, the continued effectiveness of Dalmane is a decided benefit. Even at the end of a 28-night medication period, patients with chronic insomnia were falling asleep faster, spending less time awake during the night, and sleeping substantially longer on Dalmane 30 mg *h.s.* than on baseline placebo nights (average results). This effectiveness was proved[2] and confirmed[3] in two independent sleep research studies using a new 47-night protocol. When similarly evaluated, pentobarbital was ineffective at the end of two weeks.[2]

TOTAL SLEEP TIME (MEAN)[3]
(5 patients with insomnia)

*Significantly increased over baseline placebo ($P < .05$).

In previous studies[1] chloral hydrate and glutethimide lost most or all effectiveness

In fact, continued effectiveness for both inducing and maintaining sleep over 14 consecutive nights[1] has long been an exclusive benefit of Dalmane. No other available sleep agent, including chloral hydrate or glutethimide,[1] has been able to demonstrate such effectiveness in the sleep research laboratory.

The safety record of Dalmane (flurazepam HCl) is well established

Dalmane is relatively safe and well tolerated. Prolonged administration is not generally necessary, but if used repeatedly, periodic blood counts and liver and kidney function tests should be performed.

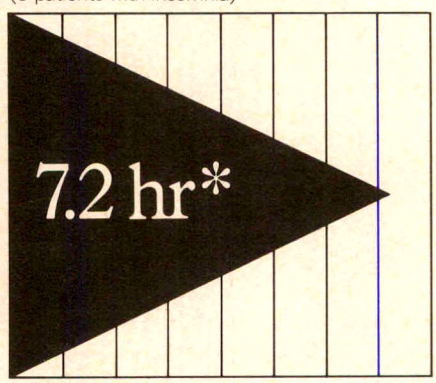
Dalmane®
(flurazepam HCl)
relatively safe... no need to increase dosage.

ROCHE

Please see following page for a summary of complete product information.

1,5,7,14,28 nights... as needed, the effectiveness of Dalmane® one *h.s.* (flurazepam HCl) C-IV meets the challenge of insomnia

One 30-mg capsule *h.s.*—usual adult dosage (15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.



■ Patients fall asleep rapidly, sleep longer on a single *h.s.* dose.

■ Nighttime awakenings and time spent awake are reduced

■ Effectiveness maintained without dosage increase from night to night

■ Patients generally awaken refreshed; morning "hangover" is infrequent

TOTAL SLEEP TIME (OVERALL MEAN)[3]
(5 patients with insomnia)

DALMANE (flurazepam HCl)
NIGHTS 1-3, 12-14, 26-28

Before prescribing Dalmane (flurazepam HCl), please consult complete product information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

*Significantly increased over baseline placebo ($P < .05$).

In clinically significant depression

TABLETS, 5 mg and 10 mg

Vivactil®*

(Protriptyline HCl | MSD)

When you want an antidepressant that is characteristically nonsedating for the patient under close medical supervision (Symptoms such as anxiety or agitation may be aggravated.)

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information please see following page.

In clinically significant depression

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl|MSD)

Contraindications: Known hypersensitivity; acute recovery phase following myocardial infarction. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe convulsions, and deaths have occurred in patients receiving tricyclic antidepressant and MAOI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, a minimum of 14 days should be allowed to elapse after the latter is discontinued. Protriptyline HCl should then be initiated cautiously with gradual increase in dosage until optimum response is achieved.

Warnings: May block the antihypertensive effect of guanethidine or similarly acting compounds. May impair mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Should be used with caution in patients with a history of seizures and, because of its autonomic activity, in patients with a tendency to urinary retention or increased intraocular tension.

Tachycardia and postural hypotension may occur more frequently than with other antidepressant drugs. Should be used with caution in elderly patients and patients with cardiovascular disorders; such patients should be observed closely because of the tendency of the drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the conduction time. Myocardial infarction and stroke have occurred with drugs of this class. On rare occasions, hyperthyroid patients or those receiving thyroid medication may develop arrhythmias when this drug is given.

Usage in Children: Not recommended for use in children because safety and effectiveness in the pediatric age group have not been established.

Usage in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, use in pregnant women, nursing mothers, or women who may become pregnant requires that possible benefits be weighed against possible hazards to mother and child.

Precautions: When protriptyline HCl is used to treat the depressive component of schizophrenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, depressed patients may experience a shift toward the manic phase; paranoid delusions, with or without associated hostility, may be exaggerated. In any of these circumstances, it may be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug concurrently. Symptoms, such as anxiety or agitation, may be aggravated in overactive or agitated patients.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. May enhance response to alcohol and effects of barbiturates and other CNS depressants. Possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have access to large quantities of the drug. Concurrent administration with electroshock therapy may increase hazards of therapy; such treatment should be limited to patients for whom it is essential. Discontinue drug several days before elective surgery, if possible. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions which have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when protriptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation and anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions, anxiety, restlessness, agitation; insomnia, panic, and nightmares; hypomania; exacerbation of psychosis.

Neurological: numbness, tingling, and paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns, tinnitus.

Anticholinergic: dry mouth and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of the urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (general, or of face and tongue), drug fever.

Hematologic: bone marrow depression; agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of other tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit packages of 100 and bottles of 100 and 1000.

For more detailed information, consult your MSD representative or see full prescribing information.

DRUG TREATMENT OF MENTAL DISORDERS

Edited by Lance L. Simpson

This authoritative and readable text considers those drugs used most often and with notable therapeutic success. Within this context, each drug is described in accordance with our current knowledge of its basic and clinical pharmacology, with emphasis placed on those aspects of drug action that have therapeutic significance. Where appropriate, current concepts of the biological basis of mental disorders are discussed. This is a text to be read and reread by students and residents, and to be used for frequent consultation by every prescribing clinician. **336 pages, Library edition: $19.75, Text edition: $13.50 (1976)**

CANCER: THE BEHAVIORAL DIMENSIONS

A National Cancer Institute Monograph

Edited by Joseph W. Cullen, Bernard H. Fox, and Ruby N. Isom

This unique volume identifies and explores the human behavioral components of cancer prevention, detection, diagnosis, treatment, rehabilitation, and continuing care. Chapters are by recognized authorities in oncology, epidemiology, psychiatry, psychology, sociology, social work, public health, nursing, health education, and communications. Comments and insights by cancer patients are an important added feature of the book. **408 pages, $17.50 (1976)**

BIOLOGICAL FOUNDATIONS OF PSYCHIATRY (2 volumes)

Edited by Robert G. Grenell and Sabit Gabay

This authoritative multiauthored set summarizes the current state of our knowledge of the biological bases of mental disorders. It examines the fundamental mechanics of behavior on the basis of the medical model. Major sections of the books are devoted to the genetics of psychiatric disorders, physiology and behavior, drive and motivation, levels of consciousness, biochemical correlates of behavior, psychopharmacology, and the biology of psychosomatic illness. **Volume 1: 614 pages, Volume 2: 478 pages, $35.00 per volume (1976)**

PHARMACOLOGY OF MARIHUANA

Edited by Monique C. Braude and Stephen Szara

This monograph, sponsored by the National Institute on Drug Abuse, is the most complete and up-to-date treatment of the pharmacology of marihuana ever to be released. Outstanding researchers have reviewed the current scientific data on cannabis and its derivatives. The volumes are a basic reference source for experimental and clinical research in the field. **Volume 1: 475 pages, Volume 2: 426 pages, Set price: $50.00 (1976)**

BIOLOGY OF THE MAJOR PSYCHOSES: A Comparative Analysis

Association for Research in Nervous and Mental Disease, Research Publications, Volume 54

Edited by Daniel X. Freedman

This volume integrates recent research in diagnosis and biology, cutting across traditional diagnostic lines, using a comparative approach to determine what can be learned from the clinical phenomena about the meaning of biological measures with respect to etiology, predisposition, clinical state, course, and outcome. **384 pages, $22.50 (1975)**

PSYCHOLOGICAL ASPECTS OF A FIRST PREGNANCY AND EARLY POSTNATAL ADAPTATION

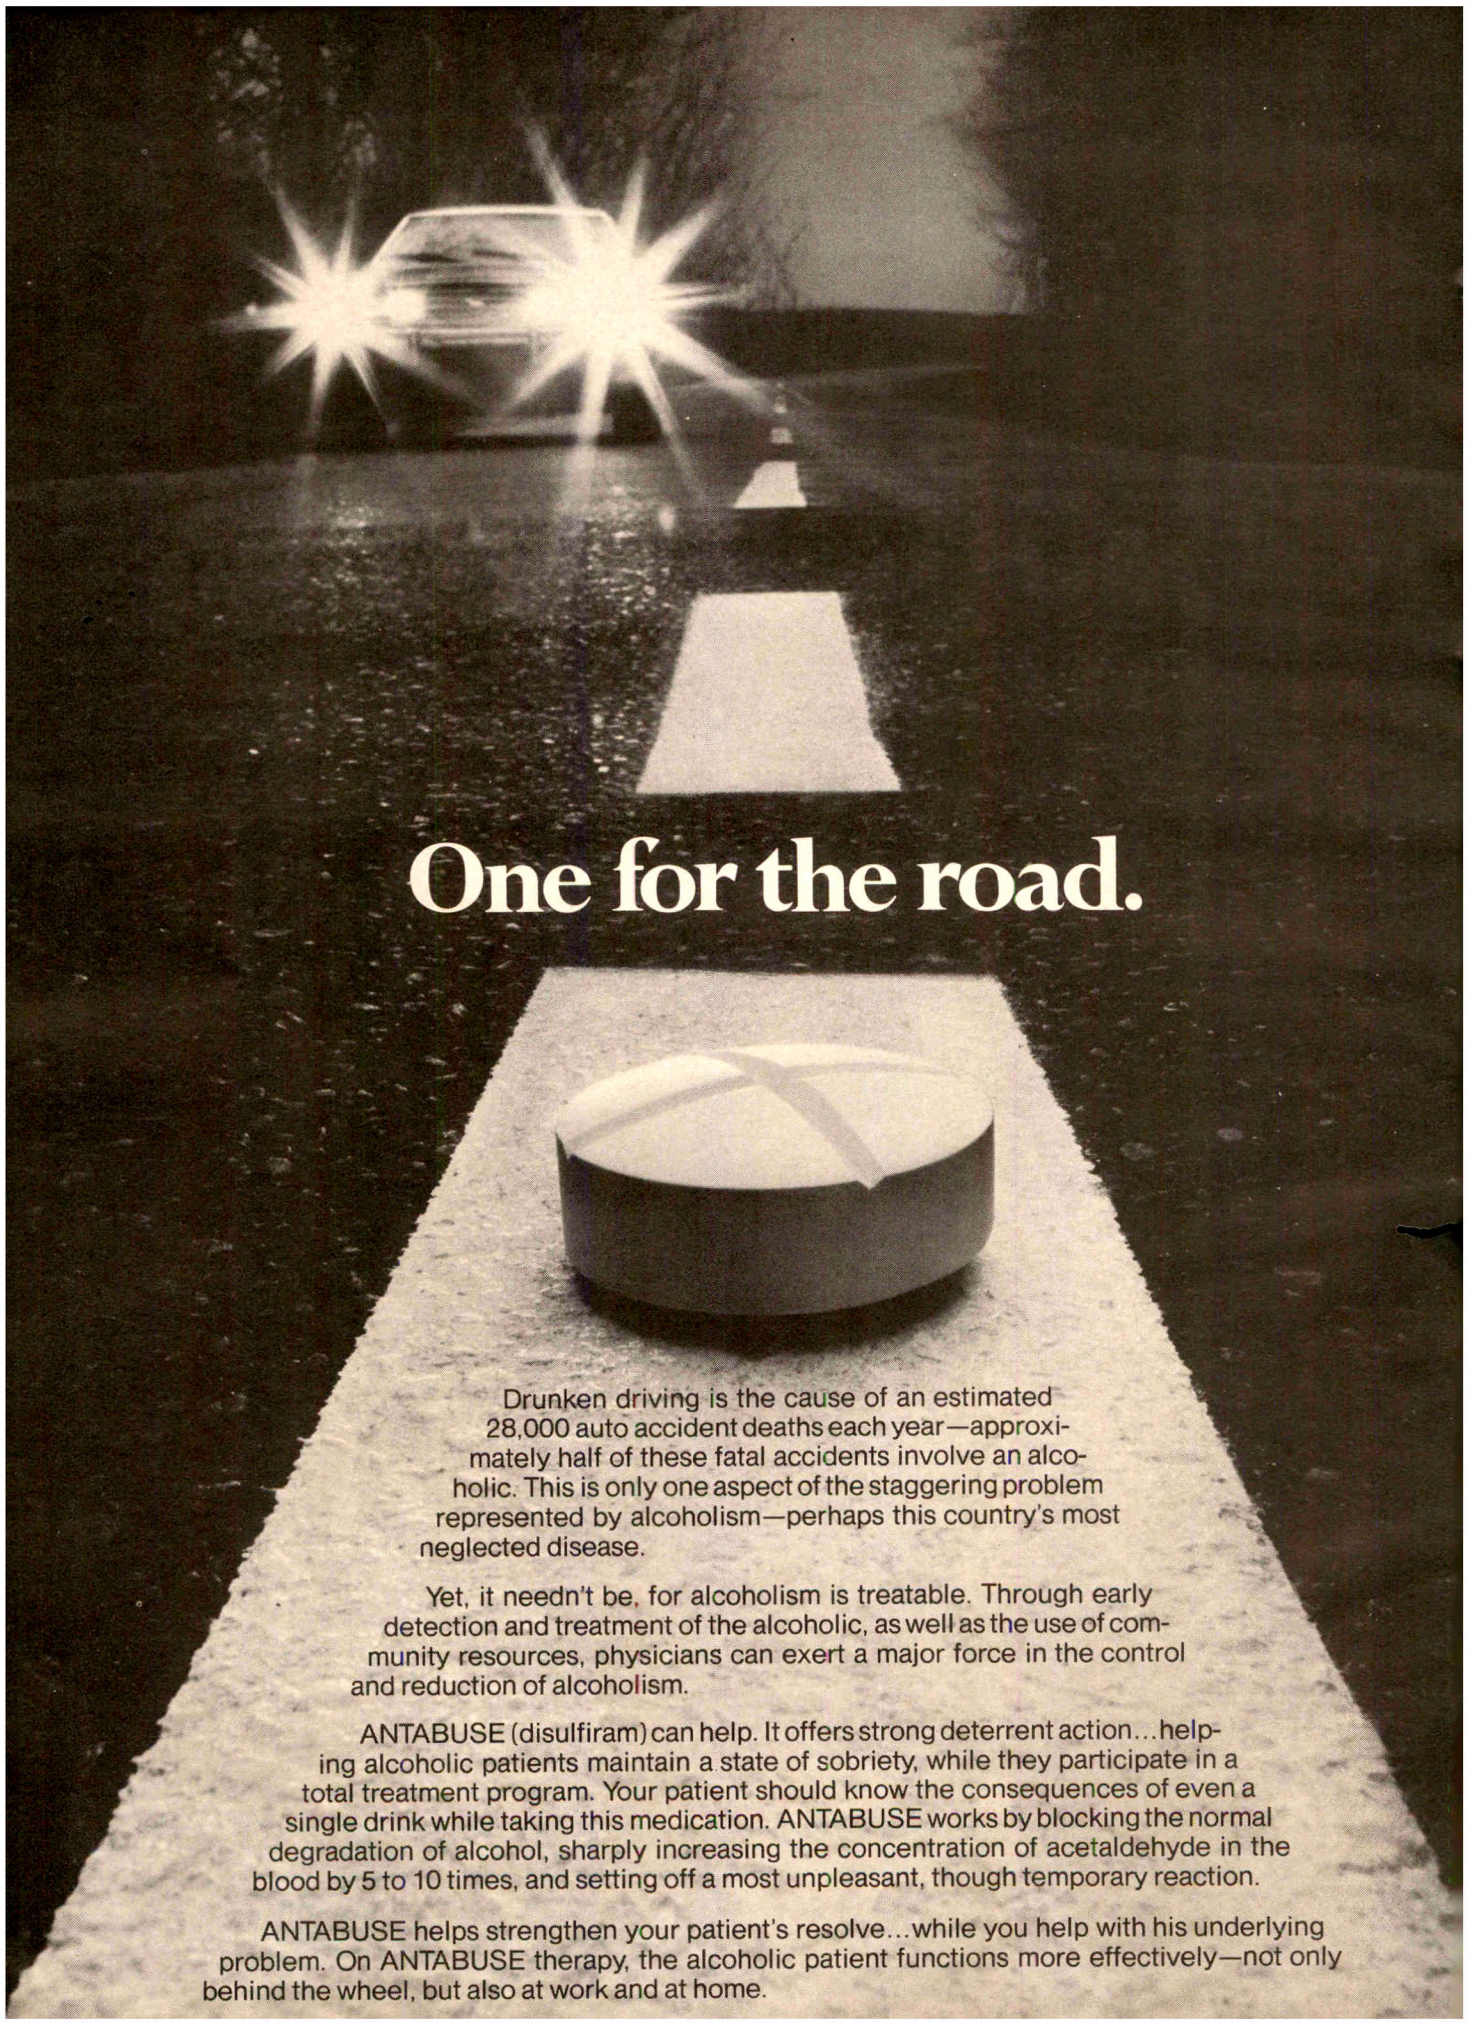
Edited by Pauline M. Shereshefsky and Leon J. Yarrow

"Presents in detail the findings of an intensive multidisciplinary study of 60 young, middle-class American families living in an urban setting. Each family was involved from three months prenatally during the course of their first pregnancy until six months postnatally. . . . The data are here—exhaustively collected, critically analyzed, and highly significant." — MODERN MEDICINE. **391 pages, $15.00 (1973)**

HORMONES, BEHAVIOR, AND PSYCHOPATHOLOGY

Edited by Edward J. Sachar

This study of the interrelationships between psychiatry and endocrinology draws on new techniques in psychologic assessment, endocrine biochemistry, hormonal and neuropharmacologic manipulation, and neurochemical analysis to clarify old problems and to discover previously unsuspected relationships. The results of these studies have important implications for psychiatric diagnosis, and for the strategy of therapeutic intervention. **326 pages, $23.75 (1976)**



FACTORS IN DEPRESSION

Edited by Nathan S. Kline

"Almost without exception, the papers in this book are comprehensive and thought-provoking articles written by innovators in several major areas of investigation. . . . The authors have a large stake in the work to which they have devoted their lives, and therefore this is also a book of opinions, seldom explicitly stated, about how we should look at depression."—American Journal of Psychiatry. **284 pages, $17.50 (1974)**

RAVEN PRESS, PUBLISHERS
Dept. JP
1140 Avenue of the Americas
New York, New York 10036 U.S.A.

Drunken driving is the cause of an estimated 28,000 auto accident deaths each year—approximately half of these fatal accidents involve an alcoholic. This is only one aspect of the staggering problem represented by alcoholism—perhaps this country's most neglected disease.

Yet, it needn't be, for alcoholism is treatable. Through early detection and treatment of the alcoholic, as well as the use of community resources, physicians can exert a major force in the control and reduction of alcoholism.

ANTABUSE (disulfiram) can help. It offers strong deterrent action...helping alcoholic patients maintain a state of sobriety, while they participate in a total treatment program. Your patient should know the consequences of even a single drink while taking this medication. ANTABUSE works by blocking the normal degradation of alcohol, sharply increasing the concentration of acetaldehyde in the blood by 5 to 10 times, and setting off a most unpleasant, though temporary reaction.

ANTABUSE helps strengthen your patient's resolve...while you help with his underlying problem. On ANTABUSE therapy, the alcoholic patient functions more effectively—not only behind the wheel, but also at work and at home.

BRIEF SUMMARY
(For full prescribing information, see package circular.)
ANTABUSE® (disulfiram) In Alcoholism
INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)
CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, *e.g.* cough syrups, tonics, and the like, should not be given ANTABUSE.
ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.

WARNINGS: ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.
The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.
THE ANTABUSE-ALCOHOL REACTION:
ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.
The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.
The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.
DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.
Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.
It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.
Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.
CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.
USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.
PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)
Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.
Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.
ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)
Optic neuritis, peripheral neuritis, and polyneuritis may occur following administration of ANTABUSE.
Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.
In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.
Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.
One case of cholestatic hepatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.
DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.
INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.
MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.
NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE, report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.
DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years.
TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, such a test reaction should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.
However, where a test reaction is deemed necessary, the suggested procedure is as follows:
After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (1/2 oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops, no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.
MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokalemia has been reported.
HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100.
No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000. **7626**

"...a considerable decrease of hyperactivity...."[1]
Knobel, 1962

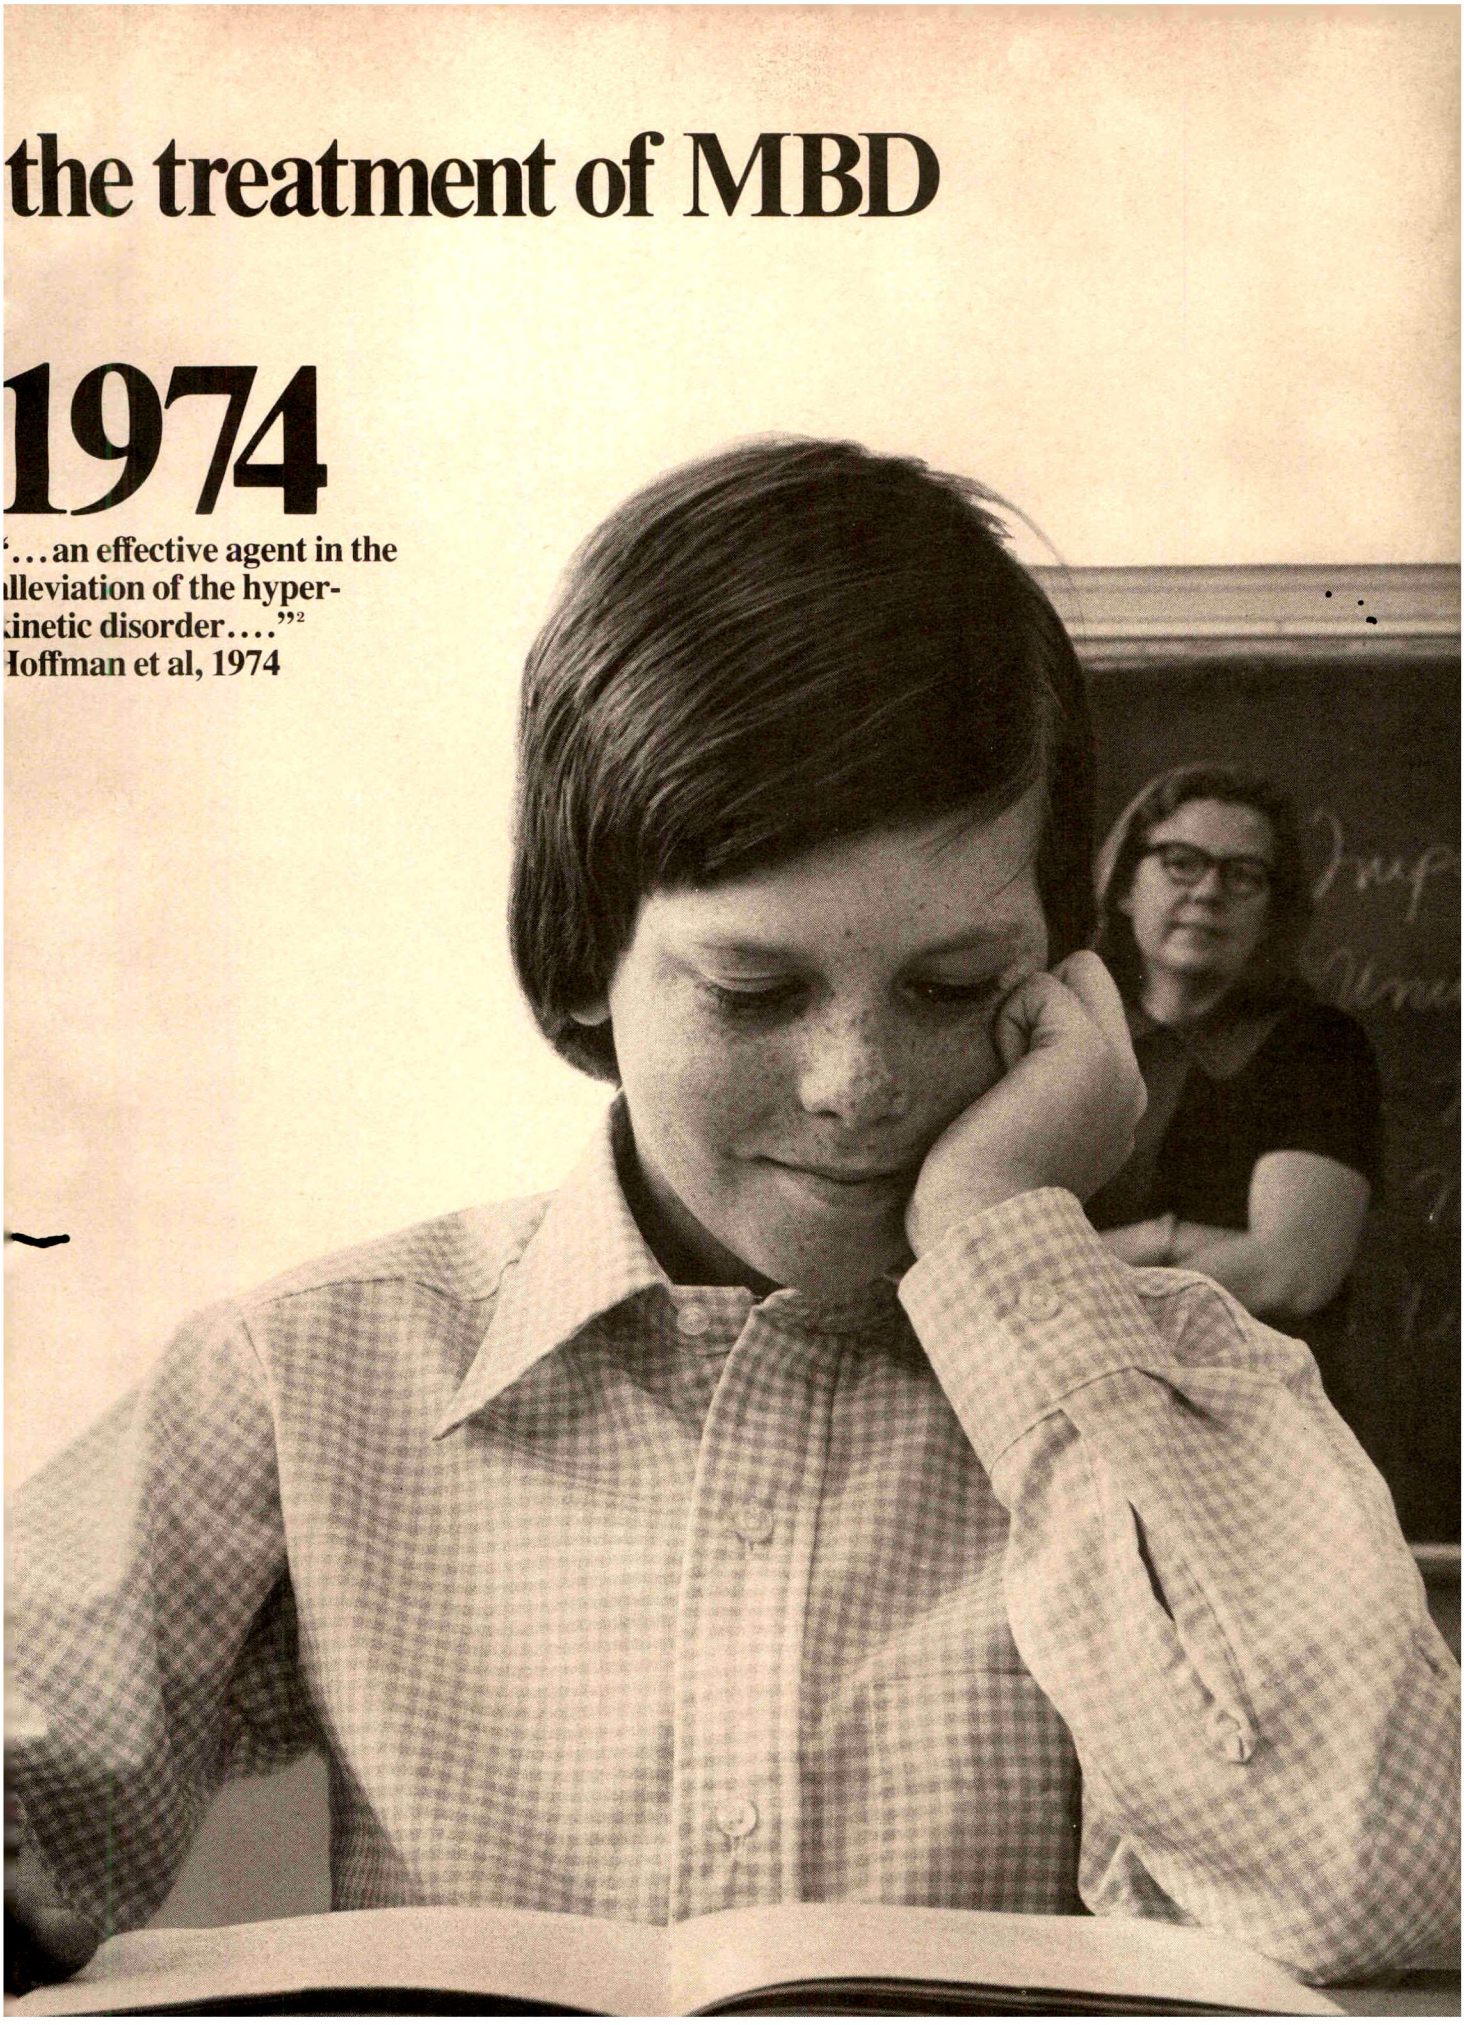
Over a decade of controlled studies and clinical experience has shown the effectiveness of Ritalin in reducing the hyperactivity,[1-3] distractibility,[1,4,5] and disorganized behavior[1-8] in the MBD child.

By lessening the effects of motor and attentional disorders, Ritalin can help the MBD child to better focus his attention on meaningful stimuli and thus can often improve cognition and promote learning.[6,9]

And side effects – insomnia an appetite loss – with Ritalin have occurred less frequently than with dextroamphetamine.[10,11]

Indeed, Ritalin is currently a drug of choice in many MBD situations,[10,12] and can prove to be an important element in many complete remedial programs for MBD.

Therapy with Ritalin should b undertaken only after a medical diagnosis of MBD has been made. Drug treatment is not indicated for all children with MBD.



Dosage should be periodically interrupted. Often, these interruptions reveal some "stabilization" in the child's behavior even without medication, permitting a reduction in dosage and eventual discontinuance of drug therapy.

(methylphenidate hydrochloride)

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak® blister units of 100.

Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

FRESH PERSPECTIVES FROM

WILLIAMS & WILKINS

428 E. PRESTON STREET
BALTIMORE, MARYLAND 21202

Clinical Geropsychiatry
by Adrian Verwoerdt, M.D.

Providing mental health services for the aged is rapidly becoming an urgent concern for psychiatrists working within the gerontological specialties.

CLINICAL GEROPSYCHIATRY is an insightful and ultimately indispensable guide to the problems attributed to the aging personality. Working within a medical-psychological framework, Dr. Verwoerdt has based his consideration on the biological, psychological, and social levels of human activity. His presentation of theoretical concepts serves to facilitate a better understanding of the psychopathology of growing old as well as an approach to treatment focusing on the origins of those symptoms associated with aging.

The material is organized into 22 chapters, each covering a separate and distinct facet of aging, supplemented with a list of references and suggestions for further study.

1976/325 pages/$16.95

Clinical Management of Sexual Disorders
edited by Jon Meyer, M.D.

In preparing this text, Dr. Meyer has met the need for a single volume containing the best of recent thought on remedial therapy for patients with sexual disorders including the determination of significant variables in sexual conditions, and the application of selected treatment techniques.

Each phase of the treatment process is adequately presented from the perspective of one or more well-qualified authorities on their particular subject. The nineteen contributors have provided thorough documentation so that anyone interested in further pursuit of the subject may easily know where to begin the search.

Addressed to no particular specialty, this volume will provide a valuable supplement to the skills of any clinician or practitioner who must regularly confront the problems associated with sexual dysfunction.

1976/about 300 pages/illustrated/ $14.95

Comprehensive Textbook of Psychiatry II (CTP-II)
edited by Alfred M. Freedman, M.D., Harold T. Kaplan, M.D., and Benjamin J. Sadock, M.D.

In this two volume, second edition of the highly regarded COMPREHENSIVE TEXTBOOK OF PSYCHIATRY, the editors have successfully performed the prodigious task of molding the knowledge and experience of more than 200 distinguished practicing psychiatric scholars into a new standard for comprehensive texts. This is one of those rare works that actually lives up to the promise of its title in that it presents the full scope of its subject from a theoretical as well as a clinical perspective.

This truly encyclopedic reference has already been recognized as the one title just as indispensable to the student as it is to the established practitioner or teacher. The achievement of CTP-II will be of interest to everyone concerned with the foundations, progress, and future of contemporary psychiatry.

1975/3000 pages/471 illustrations/$79.50

The Sexual Experience
edited by Benjamin J. Sadock, M.D., Harold I. Kaplan, M.D., Alfred M. Freedman, M.D.

The editors have called on 47 of the most knowledgeable and experienced authorities on sexuality to present this subject in all its richness and contradiction. No perspective has been denied in this unprecedented contribution to the literature of sexuality. In addition to perceptive discussions of sexual development, behavior, and identity, the text includes clinical reviews of the latest research on sex and medicine, marriage, and mental illness. Of special interest are several articles unique in their expanse of detail on such relevant topics as sex and the arts, sex legislation, pornography, and prostitution. A brilliant essay on the women's movement enumerates the effects of the movement on the social and economic circumstances of female life and thus on the changing nature of female sexual behavior.

1976/about 700 pages/117 illustrations, 14 tables/ $23.50

Human Sexuality
A Health Practitioner's Text
by Richard Green, M.D.

An unusual sourcebook with strong clinical flavor, this book is aimed at the physician, medical student, or other health service professional needing a quick reference for use in counseling patients with sex oriented questions or complaints.

Green provides factual information on birth control, homosexuality, sex assignment, heterosexual relationships, and sexual behavior during pregnancy and in cardiac or mentally retarded patients. Throughout the text, he emphasizes the importance of attitudes and techniques that will serve the patient's need for dignity and the clinician's need for gathering information.

The increased sensitivity and adequacy of response that can be achieved through an understanding of human sexuality as revealed in these pages will permit the physician to offer honest sexual advice, free of the distortion of moral judgement.

1975/312 pages/illustrated/$14.50 (hardbound), $9.50 (paperbound)

Medical Aspects of Human Sexuality
750 Questions Answered By 500 Authorities
compiled by Harold I. Lief, M.D.

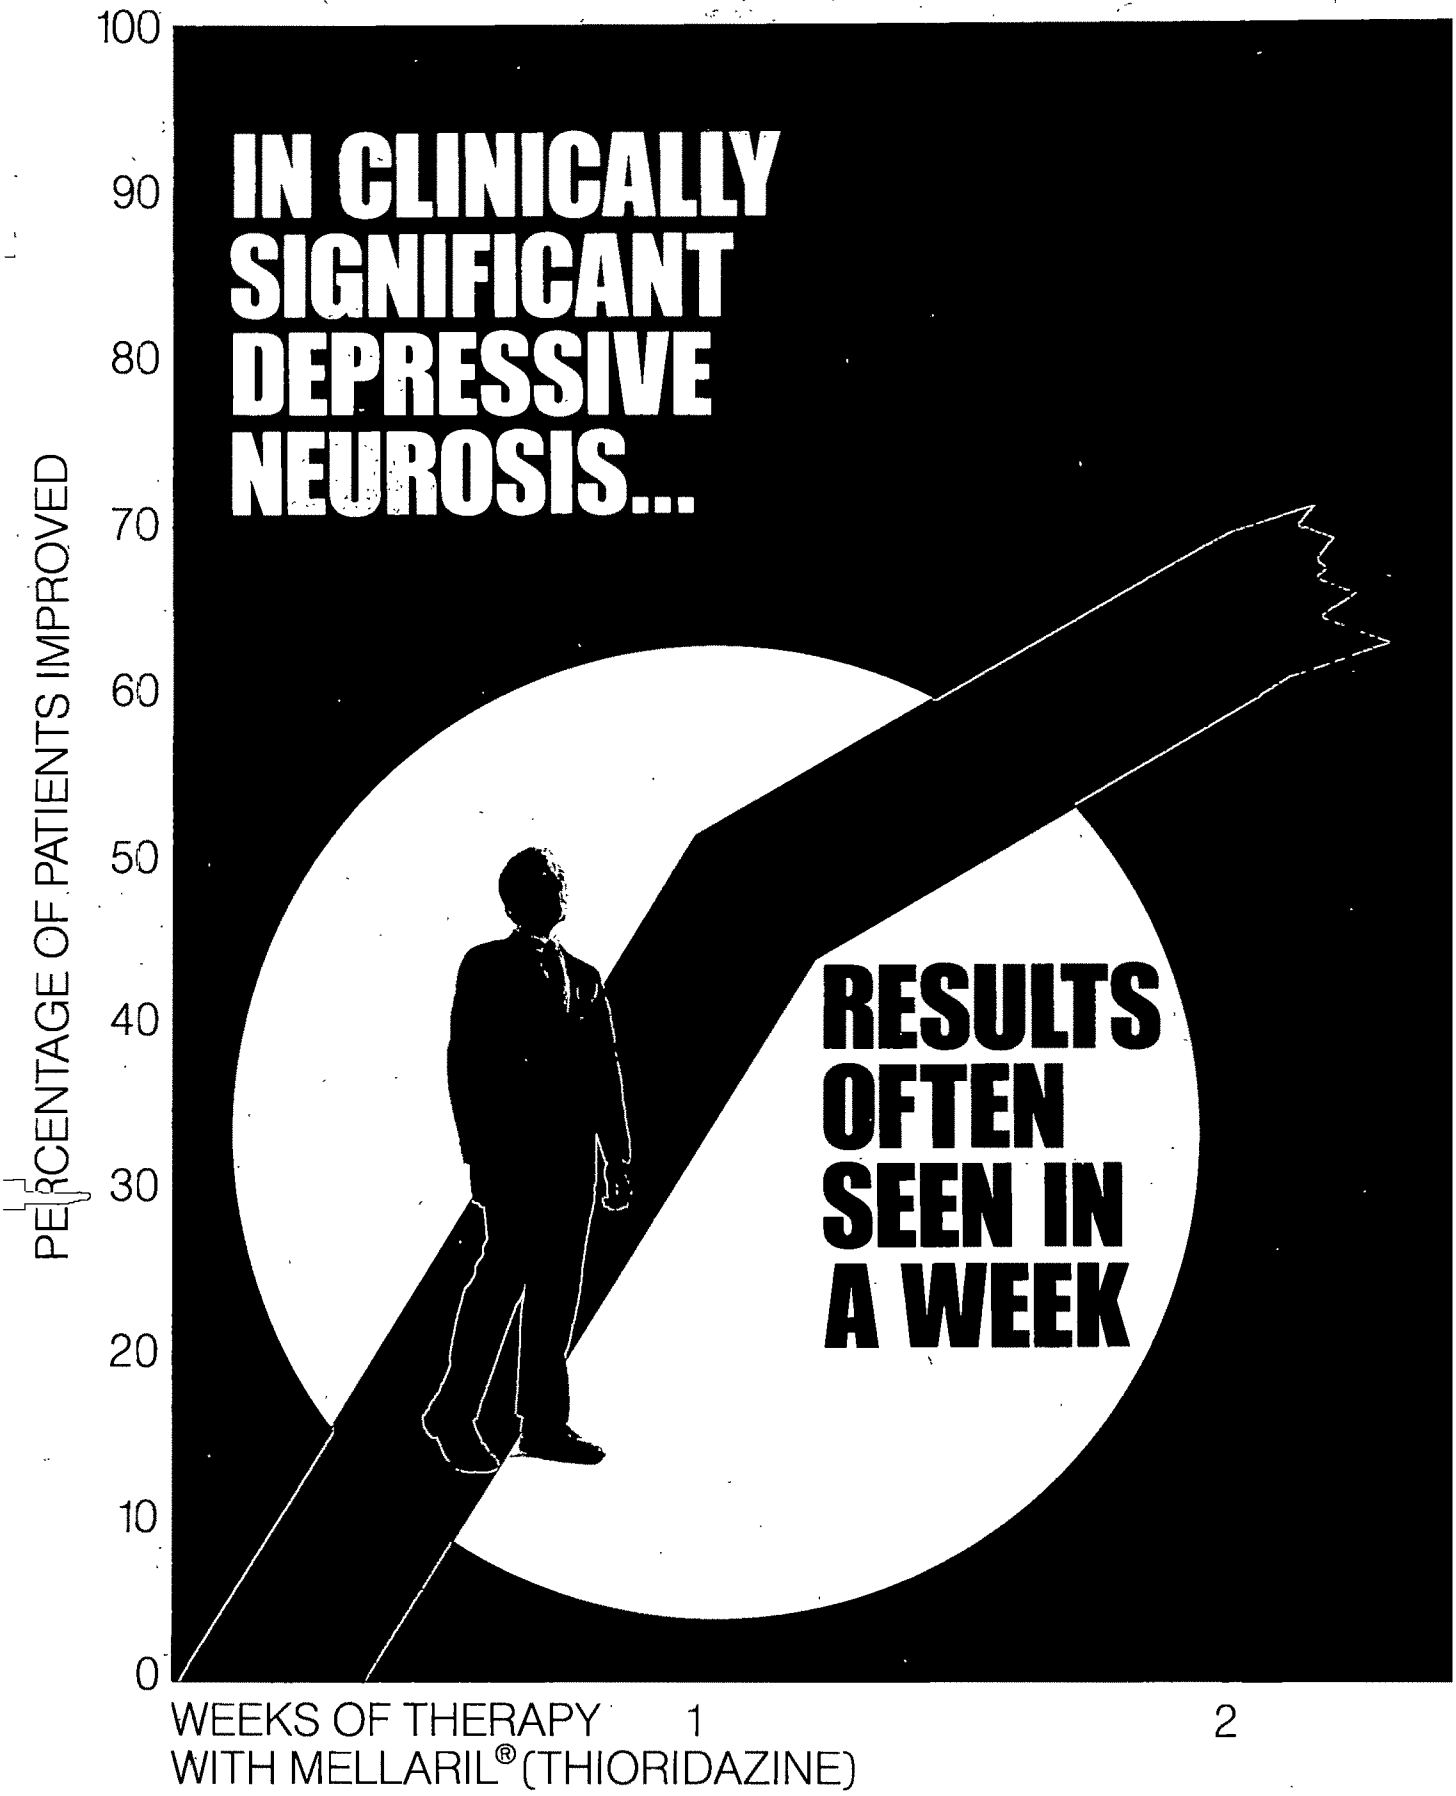
MEDICAL ASPECTS OF HUMAN SEXUALITY was written on the premise that sex related problems are the proper concern of everyone caring for the psychological or physiological well being of their patients. Neither didactic nor casual in approach, it provides authoritative responses to the questions most frequently encountered in daily practice. The question and answer format permits the inclusion of several views on those problems for which empirical studies have provided inconclusive results.

In this thorough and sensitive collection of informed dialogue from the journal of the same name, every detail of the sexual experience is considered. The topics range from basic questions on physiology and anatomy to the complex issues involved with sexual dysfunction, deviancy, marital relationships, venereal disease, and sex roles in modern society.

For the concerned practitioner, student, or researcher it will prove to be an excellent source of straightforward, factual assistance.

1975/372 pages/$14.00

Everybody knows somebody who's been helped.



The United Way is reaching out. It goes into every neighborhood. To every age group. Across every income level.
To help. In a thousand ways.
A neighbor. A relative. Maybe someone down the street who's out of work. Or sick. Or in trouble.
Chances are the United Way helps someone you know.
Maybe someday it'll be helping you.

Thanks to you it works...

For details of study and brief summary, please see following page.

Mellaril (thioridazine) can help you cope with the problem of depressive neurosis because it often produces measurable improvement by the end of the first week of therapy. In 14 double-blind studies, 339 patients with depressive neurosis received Mellaril for four weeks. In these studies, 174 patients (51.3%) improved measurably by the end of the first week, and a total of 293 (86.4%) improved during the four weeks of therapy. Furthermore, 55% of the overall improvement was observed by the end of the first week.

Mellaril usually does not cause euphoria or undue sedation and is not habituating. Patients, therefore, generally remain alert and better able to respond to therapy. The physician should, however, caution patients against participating in activities which require complete mental alertness, e.g., driving.)

MELLARIL®
(thioridazine)

TABLETS: 10 mg, 15 mg, 25 mg, and 100 mg thioridazine HCl, U.S.P.

or the short-term treatment of moderate to marked depression with variable degrees of anxiety in patients with depressive neurosis

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

Dosage: Dosage must be individualized according to the degree of mental and emotional disturbance, and the smallest effective dosage should be determined for each patient. In adults with depressive neurosis the usual starting dosage is 25 mg t.i.d. and the dosage ranges from 10 mg b.i.d. to q.i.d. in milder cases to 50 mg t.i.d. or q.i.d. for more severely disturbed patients; the total daily dose ranges from 20 mg to a maximum of 200 mg.

THE AMERICAN JOURNAL OF PSYCHIATRY

Overview: Research on the Psychology of Women. I. Gender Differences and Sexual and Reproductive Life

BY ANNE M. SEIDEN, M.D.

There has been a recent and rapid increase in research literature pertaining to women; this revolution in women's studies may be currently unequaled in any other field related to psychiatry. In this first part of a two-part article the author briefly discusses the social and intellectual contexts of research in this area. She reviews recent research on gender differences in behavior and on women's sexual and reproductive lives, including various aspects of the menstrual cycle, menopause, diseases of the reproductive organs, coitus, rape, childbirth, lactation, and fertility control. The second part will cover research on women in families, communities, work, and psychotherapy; and it will attempt to assess limitations of present knowledge and the anticipated directions and impact of future research.

> That is all I had to say to you about femininity. It is certainly incomplete and fragmentary and does not always sound friendly. But do not forget that I have only been describing women in so far as their nature is determined by their sexual function. It is true that influence extends very far; but we do not overlook the fact that an individual woman may be a human being in other respects as well. If you want to know more about femininity, enquire from your own experiences of life, or turn to the poets, or wait until science can give you deeper and more coherent information. (p. 135)
>
> —SIGMUND FREUD (1)

RESEARCH IN THE AREA that is now identified as "women's studies" has expanded exponentially over the past decade. Cutting across the social sciences, the humanities, and the biomedical sciences, the field of women's studies has characteristics of both an academic discipline and a social movement. This review will emphasize research within the fields of psychology and psychiatry and, to a certain extent, sociology and physiology. However, it is critical to note that much of the current research is being stimulated, conducted, funded, evaluated, and disseminated within the context of the broader interdisciplinary field of women's studies. The social and political, as well as the scientific, context of this field is important in both the production and the understanding of the research.

The recent knowledge explosion in women's studies is probably unequaled in any other discipline related to psychiatry. The term itself, "women's studies," was apparently first used about 1969 (2). In 1969 there were 2 university women's studies programs. By 1974, 900 institutions and 4,224 individuals were offering 4,658 courses in this area, with formal programs (one-third of them degree-granting) in 112 institutions (3, pp. vi–ix; 4). Nine volumes of synopses of women's studies courses have been published by KNOW, Inc. (5), and the Feminist Press (6). The latter maintains a clearinghouse on women's studies and publishes both a *Women's Studies Newsletter* and a guide to courses, programs, and teachers (3). Representative scholarly journals in this area include *Feminist Studies, Women's Studies, Sex Roles, Journal of the Psychology of Women, Journal of Women and Health*, and *Signs: Journal of Women in Culture and Society*. A number of standard professional journals, in or pertinent to the field of psychiatry, have recently included special issues or

This paper was written at the invitation of the Editor.

Dr. Seiden is Director of Research, Institute for Juvenile Research, Illinois Department of Mental Health and Developmental Disabilities, 1140 South Paulina St., Chicago, Ill. 60612. She is also Assistant Professor, Department of Psychiatry, Abraham Lincoln School of Medicine and School of Public Health, University of Illinois, Chicago, Ill.

The author wishes to thank Shiaomay Young, M.A., for bibliographical research, Marlyn Grossman, Ph.D., for editorial assistance, Estelle Marvel and Joann Brown for manuscript preparation, and a number of colleagues who provided valuable stimulation and suggestions at various stages in the preparation of this paper.

special sections on women's issues within their disciplines (7–12).

There has been sufficient publication in this area to justify the existence, since 1972, of two separate bibliographical periodicals, *Women's Studies Abstracts* and the *Canadian Newsletter of Research on Women* (which emphasizes non-U.S. sources). A number of annotated bibliographies have been published in specific areas related to women's issues, such as health, education, and mental health, including two research bibliographies from the National Institute of Mental Health (13, 14), one from the American Psychological Association (15), and a general one by Davis (16). Hochschild (17) reviewed the literature on sex roles and Long-Laws (18) the marital therapy literature, from a feminist perspective. In 1974 Eichler (19) published an annotated bibliography of bibliographies on women, and Astin and associates (20) added one on education and career issues. Daniels (21), commissioned by the Association of American Colleges' Project on the Status and Education of Women, surveyed existing research findings, persistent research questions, and sources for keeping up with this expanded flow of research.

In 1975 the *Annual Review of Psychology* for the first time included a section on the psychology of women (22). In contrast, Tennov (23) noted that of 35 introductory texts in social psychology published between 1940 and 1970, only 1 had a chapter concerning women.

More recently, several major texts on the psychology of women have appeared (24, 25), as well as several collections of readings suitable for textbook use (26–29). Earlier, but still classics, are Morgan's collection (30), which contains a number of important scientific as well as general articles, and Cade's collection of work on black women (31). Also important are several histories of the current women's movement (32), of male and female sex roles (33–35), and three archival collections of important historical documents (36–38). Two histories of childhood (39, 40) and one collection of archival sources on childhood (41) also contain historical research pertinent to women.

It is of interest that relatively little of this knowledge has thus far been directly incorporated into psychiatric teaching programs. In a 1973 survey, the American Psychiatric Association's Task Force on Women found that only 26 of the 167 residency programs responding offered course work in the psychology of women, sex roles, or related topics (less than the number offering courses dealing with ethnic minorities); most of these courses were elective rather than required (42). Major textbooks on psychiatry have not dealt extensively with the women's movement or with women's studies as such (although the current second editions of the books by Freedman and associates [43] and Arieti [44] are exceptions). While the 1974 examinations of the American Board of Psychiatry and Neurology and the APA's 1972 Psychiatric Knowledge and Skills Self-Assessment Program included a number of questions related to other social psychiatry issues, they did not examine in this area.

Clearly, the very newness of much of the work in this area accounts for its present relative absence from psychiatric curricula. Time is required for new research to be read, replicated, critically reviewed, and assimilated. When in addition the area in question is one that is as personally and professionally heavily loaded as this one, there may be some sources of caution or resistance that further delay the process. A psychiatrist's views of what women are or ought to be are rather obviously likely to have a more profound effect on one's personal life and world view than, for example, a double-blind study comparing the effects of two different neuroleptic agents. We bring our hopes and fears in this area to our design and evaluation of research results as surely as we do to our clinical work. Roeske's review of women in psychiatry (45) highlighted how often the psychiatric implications of gender issues have been handled by denial in clinical and training situations. That same denial may bias research by affecting the choice of research topics or subjects, the ways in which questions are asked, and the ways in which data are interpreted. Methodological problems are many and sometimes complex.

Nevertheless, there already exists a considerable body of new research that is of great importance to psychiatry. This overview will highlight major findings in selected aspects of this large area and will conclude with an assessment of the impact and limitations of the data and their present and future importance to psychiatry.[1]

RESEARCH ON SEX DIFFERENCES

A vast amount of research has been conducted in an attempt to determine the nature and extent of sex differences. Much of this work has been carefully reviewed in a major book by Maccoby and Jacklin (48); their annotated bibliography cites approximately 1,500 studies appearing between 1966 and 1973 alone. Earlier studies in this area were reviewed by Mac-

[1]Conceptually parallel to the growth of women's studies is the more recently developing field of men's studies, properly the subject of another overview article. As with women's studies, it is both an academic research field and a social movement. As the latter it seeks to counteract aspects of male gender role that seem to be associated with considerable, even lethal, consequences for the individual or society. As a research field it has many of the goals of women's studies—to correct prior research biases by treating male human behavior as a subject of inquiry in its own right, separate from the assumption that male behavior is more "representative" or "normative" for humans than female behavior.

Currently, there are far fewer courses and publications in this area, but the number appears to be growing. Representative books include Filene's (33) from a historical perspective, Pleck and Sawyer's (46) from a social science background, and Farrel's (47) for general readers. A *Men's Awareness Network Newsletter* is published by the Knoxville, Tenn., Men's Resource Center and cites scholarly and social resources. In 1975 it listed five college courses on men or male roles, one men's studies program in a "free college," and one major bibliographical collection (the Men's Studies Collection in the Charles Hayden Library of the Massachusetts Institute of Technology).

coby (49), Sherman (24), Bardwick (25), and Garai and Scheinfeld (50). Clearly, the area of sex differences has attracted considerable research attention.

In principle, sex differences could arise from at least the following sources:

1. Intrinsic biological differences that are present from birth or a relatively early age.
2. Purely cultural differences in roles assigned to the sexes.
3. Anticipatory socialization, which is cultural at the time it is taught to the child but is preparatory for genuine biological differences that will not become apparent until a later age (e.g., childhood socialization for, or against, the adult experiences of childbirth and child nurture).
4. Differential value, meaning, or reward assigned by the culture to the gender-specific behaviors from sources 1, 2, and 3, causing certain types of behavior to be more strongly reinforced in a gender-specific way.
5. Further cultural elaboration of behaviors that predictably emerge as part of reactions to the more basic sources listed previously. For example, if women are differentially socialized against *direct* expression of sexuality or aggression, an elaborate secondary repertoire of *indirect* expression, sometimes called manipulation, is required.

Despite the theoretical importance of intrinsic biological differences and the considerable belief in them on a folk-wisdom basis, it is easier to demonstrate *belief* in these differences than the differences themselves. One study (51) found that fathers described their newborn daughters as "delicate" and their sons as "strong" before they had seen the children. Another study (52) found that mothers played differently with and observed different attributes in a strange child, depending on whether the child had been introduced as "Beth" or "Adam." While such beliefs can clearly become self-fulfilling prophecies, to what extent do they also rest on innate biological differences?

The difficulty is partly methodological; one cannot experimentally raise an otherwise normal human in a culture-free environment. But it is also substantive; the plasticity of human behavior is such that many biological differences can be overcome by learning. And the variability of human behavior is such that there is considerable overlap between the sexes on almost any variable chosen for comparison, with considerably more variation within than between the sexes.

Maccoby and Jacklin (48) summarized sex differences that they feel are fairly well established at this time. They are as follows:

1. Girls have, on the average, greater verbal ability than boys *after* about age 11, as measured by tasks involving both receptive and productive language. This is true for both "high-level" verbal tasks (e.g., analogies, comprehension of difficult written material, and creative writing) and "lower-level" ones (e.g., fluency).
2. Boys have, on the average, greater visual-spatial and mathematical ability beginning at about ages 12–13 and increasing through the high school years. There is some evidence that a recessive sex-linked gene contributes to greater than average spatial ability in approximately 50% of all men and 25% of all women, which of course raises the average scores for males.

Both of these sex differences begin to emerge around the time of pubertal changes, but the evidence that biological factors are contributory is stronger for visual-spatial than verbal abilities. Sex differences in mathematical abilities vary greatly among populations, probably depending somewhat on the measures that are used (with mathematical problems involving spatial concepts giving an advantage to the greater number of boys with greater spatial abilities).

3. Males are more "aggressive," with sex differences appearing as early as social play does (ages 2–2½) and appearing in both physical and verbal, direct and attenuated forms of aggression. The meaning of "aggression" is complex and will be discussed later.

Maccoby and Jacklin regarded the following as *unfounded* beliefs about sex differences: that girls are more socially oriented than boys, more suggestible, more auditory, less visual, less analytic but better at rote learning, and lower in self-esteem and achievement motivation.

They regarded the following as areas open to question because of insufficient evidence or ambiguous findings: sex differences in tactile sensitivity, fear, timidity, anxiety, activity level, competitiveness, dominance, compliance, nurturance, and "maternal" (or parenting) behavior.

The activity-passivity dimension does not appear to differentiate the sexes unless one 1) confuses activity with aggression or 2) regards activity as masculine and passivity as feminine by definition, in which case the reasoning is circular. The confusion of activity with aggression arises in part because many measures of activity occur in situations that are also likely to arouse aggression.

If aggression is defined as "the intent of one individual to hurt another, either as such or as part of an attempt to control another for other ends (by use of fear)," it does persistently appear more commonly in males. This shows up cross-culturally and in different age ranges, although most of the studies Maccoby and Jacklin reviewed were laboratory studies done with young children. It was noted that mothers use more physical punishment (itself an aggressive act by this definition) with boys than girls, possibly setting up a circular process where aggression reinforces aggression. Where this process starts is uncertain, although Maccoby and Jacklin lean toward a biological explanation.

Maccoby and Jacklin (48, p. 371) suggested that a major effect of differences in aggressiveness on vocational choice may come about by default because "women, being slower to anger, are less likely to protest onerous assignments . . . to put the matter bluntly, they are easier to exploit" and therefore may

accept less desirable vocational options.

Whatever the ultimate source, the present sex differences in aggression appear to be considerable, and there may be implications in this fact for social issues. Evidence from other sources (53, 54) indicates that some of the differences may be disappearing, with apparent increases in women of some forms of aggression, such as crimes of violence. It is possible that this kind of change, however much viewed with alarm, may have its positive aspects. The history of occupational sociology tells us that as formerly male occupations become increasingly occupied by women (e.g., schoolteachers, bank tellers), they increasingly lose their attractiveness for men. It is in fantasy conceivable that the entry of larger numbers of adolescent and young adult women into the "field" of criminal violence might in part decrease its attractiveness as an arena for "proof" of masculinity.

With reference to child rearing, animal and cross-cultural work suggested to Maccoby and Jacklin that there may be some danger to children from untamed male aggression, but "that boys who have been involved in caring for younger siblings were less aggressive with age mates as well—i.e., . . . the process of caring for children at least on a part time basis can moderate aggressive tendencies" (48, p. 372). Discussing sex role traits, these authors made the obvious point that effectiveness as a husband and father can well be diminished by a machismo role, while "training a girl to be feminine" in the traditional nonassertive "helpless" and self-deprecatory sense may actually make her a worse mother. They concluded with the hopeful note that a society might "devote its energies more toward moderating male aggression, or toward encouraging rather than discouraging male nurturance activities" (p. 374), a conclusion also voiced by Eisenberg in a paper directed at pediatricians (55).

The generalizability of the work reviewed by Maccoby and Jacklin is significantly limited by the ages of the populations studied and the nature of behaviors observed. Guided by developmental theory, psychoanalytic or otherwise, the vast majority of the studies were done on children, often very young children; only a handful were done on adults. Yet the review shows that the most stable sex differences appear *after* puberty. In a recent review of current work in child development Baer and Wright (56) discussed the implications of reinforcement models (or social learning theory) as opposed to classical developmental models; the former imply relatively greater plasticity of behavior *if* the reinforcement conditions change, while the latter imply something close to the concept of "critical periods" for acquiring behaviors such as those which constitute sex differences.

The rapidly expanding literature that explores the role of sex differences in the vicissitudes of achievement motivation essentially began with the work of Horner (57, 58). She did indeed find sex differences in late adolescents and adults, contrary to the findings for younger subjects summarized by Maccoby and Jacklin; it appears likely that reinforcement conditions of adolescent or adult life may account in large part for differences that apparently emerge after childhood. (Research on adult social roles will be further discussed in the second part of this overview.)

On the other hand, a now considerable body of clinical research on patients suffering from gender dysphorias, gender misdiagnoses, or gender changes intriguingly appears to require both developmental and reinforcement models. For example, the work of Money and Ehrhardt (59) and Stoller (60) suggests that there may be something like a critical period for the development of core gender identity (i.e., one's sense of "I am female" or "I am male"). Even when based on anatomical misdiagnosis that could be corrected, gender *identity* is presently found to be virtually irreversible after early childhood.

On the other hand, the content of gender *roles* (sex-typed behaviors) appears to be heavily based on social learning. Males who are reared as females or made to appear female can assume female role behavior convincingly enough to satisfy the average observer if certain conditions are met. These conditions ordinarily appear to include having a female gender identity fixed before a relatively critical age. The same is true for females reared as males, but it is of interest that the applications for male-to-female sex change far outnumber the applications for female-to-male change. It is not known to what extent this reflects the greater technical success of the male-to-female operation, the fact that female preponderance in child rearing makes male infants more likely to develop a female identification than are females to develop a male identification, or the possibility that the socially defined male gender role is in fact less stable, less biologically "given" and therefore "natural" and more "cultural" and ambiguous, thus more vulnerable to gender dysphoria (61).

Psychoanalytic developmental theory places heavy emphasis on the child's perception of sex and gender differences and the implications of traumatic awareness of these differences for later personality development. However, examination of female sexuality and personality is a particularly weak area in classical psychoanalytic theory, as noted by Freud (1) and Jones (62). A recent review by a noted psychoanalytic theoretician (63) concluded that "Freud's generalizations concerning girls and women do injustice to both his psychoanalytic method and his clinical findings," particularly in such essentials as equating femininity and passivity. It is of interest that in 1905 Freud published both "Three Essays on the Theory of Sexuality" (64) and the next to last case study of a woman to be included in the standard edition of his psychological work (65), although most of his case studies of men were published thereafter. In other words, his later and therefore presumably more mature theoretical thinking as applied to his own clinical work with women was not made available for review as published, detailed, clinical treatment studies.

Much of the earlier psychiatric thinking on gender

differences and identification, particularly as subjectively experienced, derives from clinical psychoanalytic studies of adult patients. The methodological problems are obvious but are not easily solved. Adults may remember poorly, but small children verbalize poorly and adult observers may easily deny, distort, or exaggerate children's sexuality (as Freud [64] observed) or inaccurately project their own feelings and experience into their observations.

There is currently a keen psychoanalytic interest in gender difference issues in general, as well as female sexuality. There have been panels on aspects of female sexuality at virtually all of the recent psychoanalytic meetings. Unfortunately, most of this work lies outside the scope of this paper, since much of it is as yet unpublished and most of it is clinical or theoretical rather than research. An exception is the work of Roiphe and Galenson (66, 67). Based on observations of infants in nurseries and on parents' reports, they have demonstrated that awareness of gender differences regularly occurs by 18 months (much earlier than classical psychoanalytic theory postulated). In their samples this awareness did tend to be somewhat traumatic, but more than a transient difficulty in assimilating it appeared to be associated with prior experiences likely to have damaged object relations or the sense of bodily integrity (such as nongenital as well as genital surgery).

RESEARCH ON SEXUAL AND REPRODUCTIVE LIFE

The Menstrual Cycle

Menarche probably marks a more clear-cut landmark in pubertal development than any single event in the adolescence of boys. The overwhelming majority of women of all ages can remember with precision the age and circumstances during which the first bleeding occurred. There is an enormous variation, of course, in the amount of intellectual understanding, anticipation, surprise, pain, affective change, and indeed the amount and regularity of bleeding that occurs with first periods. We are just beginning to get prospective data on samples of normal young women. One study (68) reported that some women have a sobering or even depressive response to first periods and begin to experience their lives as more serious or more restricted. Earlier studies (e.g., references 69–71) were based on retrospective data from adults but appear to provide general agreement.

Although menarche is a life event that could well be examined within the framework of crisis theory, and is marked by elaborate rituals in some primitive societies, our society pays relatively little public attention to it either ceremonially or in the scientific and general literature. Hygiene books for grade-school children generally omit references to menstruation. Special booklets and films provided by manufacturers of sanitary products attempt to fill this gap, with some serious omissions noted by Whisnant and associates (72).

Somewhat more data are available on the biopsychological and behavioral effects of cyclicity as such (73–83). However, work in this area must be appraised with caution. The actual biological events are covered with considerable psychological and interpersonal overlay, and there are very real consequences in individuals' lives from the hasty acceptance of overgeneralized data. The fact that some women have severe premenstrual or menstrual incapacity and others do not has been used paradoxically both 1) to dismiss the seriousness or validity of the complaints of those who do have the syndrome, and 2) to assume erroneously that if some have it, all do. For example, one politically prominent physician was willing to officially state his belief that menstrual and menopausal syndromes made women as a group unfit for political office (84). By contrast, those women who do experience severe symptoms may have difficulty obtaining indicated medical treatment for this "psychogenic" malady (85).

Effects of the menstrual cycle. With these caveats in mind, what data are currently available about the effects of the menstrual cycle? A number of studies (73–76, 81–83) appear to show increases in certain affects (i.e., libido, irritability, anger, anxiety, and/or depression) in some women during the premenstrual and menstrual phases of the cycle and corresponding decreases in the same affects at other phases. This may be manifested in such diverse measures as self-reported affects, dream content, waking fantasies, and overt behaviors including increased accidents, committing violent crimes, and more frequently bringing one's children to emergency rooms for minor illnesses. Some studies show increased and some decreased libido (73, 74).

The proportion of women reporting any of these effects varies among studies but averages about 50% (this average is undoubtedly somewhat inflated by the fact that studies showing negative effects are less likely to be published). In one series of prospective studies (75, 76), women who on entering college reported severe menstrual distress turned out to have lower grade-point averages and a greater probability of diagnosis of affective disorder, suggesting the possibility that bipolar affective disorder in women may initially present as menstrual distress. However, in a nonclinical population Sommer (77) failed to find any evidence of intellectual or performance changes with the cycle.

Methodological problems in this area are many. It is obvious that a woman's own expectations about menstruation (and possibly those of her family, friends, or sexual partners) could override purely hormonal factors. Indeed, Paige (78) found that reported menstrual distress varied with both the subject's religion and the actual amount of bleeding (itself dependent on hormonal manipulation). Koeske (79) showed that vignettes describing angry behavior by women were attributed by college student judges to environmental events unless the vignette included the information that the sub-

ject was in a premenstrual or menstrual phase, in which case the same behavior was attributed to menstrual-related tension. Parlee (80) has reexamined Dalton's data (74) showing poorer examination performance by menstruating students. The same data also provided evidence for delayed menstruation in a portion of the sample. Cycle variability is considerable, and stress can delay or accelerate ovulation and menstruation. Therefore it is possible that prolonged stressful situations, culminating in attempted suicide, violent crimes, or poor examination performance, and then a period, could sometimes represent "tension-delayed menstruation" instead of "premenstrual tension" (80).

Surprisingly, after all these centuries of human menstruation, we still do not have definitive data on the subject. It is intriguing, however, as Parlee (81) noted, that most researchers attribute behavioral or affective changes associated with the menstrual cycle to hormonal factors, but are more likely to attribute emotional changes during pregnancy to the woman's life situation or intrapsychic conflicts about motherhood, despite the fact that there are considerably greater hormonal changes associated with pregnancy.

More research in this area is clearly needed. At the present, reviews by Parlee (81), Melges and Hamburg (82), and Dalton (74), and Weideger's book for general readers (83) seem to provide the best coverage of the topic.

Effects of other types of cyclicity. While the greater visibility of cyclical changes in menstruating women has attracted more study, researchers are beginning to study the effects of cyclicity in hysterectomized women who retain their ovaries and in men (86, 87). Testosterone levels in men do vary with time, with access to sexual opportunities, and apparently on occasion with the menstrual cycle of the usual sexual partner. In rhesus monkeys, testosterone levels can be experimentally manipulated by artificially changing the male's access to estrous females or his dominance position vis-à-vis other males (88). Other studies of women have shown greater affective and behavioral fluctuation with the weekly cycle (work week versus weekends) than with the menstrual cycle (e.g., reference 89); diurnal cycles are important in affecting hormonal and affective changes in men and women. The whole topic will be more comprehensively dealt with when it can be brought together with the growing literature on circadian and ultradian rhythms in general.

Menopause

Menopause is a distinctly human characteristic. In most other mammals, the sexes do not differ greatly in their capacity for maintaining fertility up to advanced old age. The biological adaptive value would appear to be related to other distinctive human characteristics such as the prolonged period of childhood dependency, with complex care-taking behaviors that in the human are not fixed action patterns but must be learned. The existence of menopause assures that an average healthy woman will have many years of vigor and good health following the birth of her youngest child. This freedom from new pregnancies permits more extended child rearing as well as participation in a number of teaching, care-taking, and leadership functions. Selective pressures clearly appear to have favored those of our ancestors whose females had menopause over those who did not. Thus it is particularly ironic that the medical and psychiatric literature on menopause, as reviewed by Osofsky and Seidenberg (90), tends to view it as "a time of mortification, with service to the species over."

Symptoms of menopause. Symptoms attributed to the menopausal phase itself include vasomotor instability (hot flashes, night sweats) and emotional difficulties (irritability, anxiety, depression, insomnia, etc.). Symptoms attributed to the postmenopausal phase have included estrogen deficiency syndromes (vaginal mucosal thinning) and emotional difficulties, predominantly depression, with impaired self-esteem. Interestingly, we do not have generalizable data on the prevalence of these symptoms in the population at risk. One review (91) suggested that the vasomotor symptoms are more frequent in women of menopausal age than other ages, but emotional symptoms are not.

As with menstrual symptoms, there has been a paradoxical tendency to assume that if some women have severe or troublesome symptoms, all must, and conversely, to either provide inadequate treatment for the presumed "psychogenic" symptoms of those who do or prescribe unnecessary (and apparently carcinogenic) (92) estrogens even when symptoms are mild or unrelated to estrogen deficiency.

Thus far there appears to be a relative neglect of the effects of the menopause (and its anticipation) in much of the recent work on psychology of women. A number of relatively comprehensive books on women (e.g., reference 24) and sex differences (28, 48, 59, 93) do not deal with it at all, despite the fact that the relatively early end of female versus male fertility is one of the more striking sex differences in humans.

Social factors. Standard texts do not appear to include many references to cross-cultural work bearing on the important question of the extent to which menopausal symptoms are prominent in cultures in which women's social power and influence rise rather than decline with age. In any society menopausal phenomena are inevitably intertwined with other aspects of beginning middle age. Women are more likely to be widowed than are men, and if this occurs they have less chance of remarriage, a salient difference in a social structure primarily organized around the heterosexual pair bond. At about the same time as the menopausal years, many women are dealing simultaneously with the departure of children from the home, the entry of the husband (who is likely to be several years older) into the years of preretirement, and the risk of middle-age depression and even death. These factors merit study in relation to the emotional difficulties reported by some women at these ages. Social factors seem to

be at least as important as biological ones at this point. For example, the factors predictive of an active sexual life in older age groups have emerged as general good health, prior active sex life, and the availability of an interested and interesting partner (94).

Diseases of the Reproductive Organs

An aspect of body image with an important effect on the psychology of both sexes is the potential for life-threatening or life-disrupting diseases of the reproductive organs, particularly when those diseases are mysterious or related to sexual activity or both. Thus syphilophobia was apparently a far more common clinical entity when the natural history of syphilis was less well understood and its treatment less effective than they are today.

The internal position of most of the genital organs in women is generally believed to contribute to women's sexuality being perceived as more mysterious by both women and men; but for women this poses a body image problem as well. If the organs cannot be seen, their very existence and certainly their healthy functioning cannot be verified except by inference; Barnett (95) found evidence of a body-image scotoma in girls including the vagina itself and the organs within, and Whisnant and associates (72) found that adolescent girls still had extremely vague notions of just what was supposed to be where, even after receiving instruction on the subject.

Yet women who have received reasonably adequate health education (and women's magazines contain a great deal more of this than men's do) have been told of the risks of having cervical and uterine cancer and asymptomatic venereal infections: these risky conditions can only be detected by having someone else examine the woman's body and do appropriate tests. While the woman is assured that she should examine her own breasts for lumps, she is reminded that only a physician can tell if they are benign. Thus her appropriate health education, if carried out well, must inform her of the risk that these parts of her body can, as it were, turn against her in a malignant way. Whereas in past years a woman's potential fear that her own body might kill her may have been more closely associated with a fear of obstetrical catastrophes, in contemporary life the risk of death from breast or genital cancer is relatively much greater.

Like so much about women's biology, these risks are currently both overreacted to and underreacted to. That they nevertheless play an important role in women's psychology seems likely. It is quite possible that a vaguely defined fear of death or disease from genital organs has contributed to women's willingness to undergo hysterectomies far more often than is generally believed necessary. Indeed, the word itself may favor such treatment; excessive concern with ill-defined body complaints is more likely to be called "hysteria" in women, whereas comparable symptoms in men are more likely to be called "hypochondriasis" (referring literally to chest pain). On the other hand, the average adult patient visiting any physician's office with almost any complaint is likely to have the heart and lungs examined (thus detecting evidence of the prime killers of middle-aged men), while the average woman, unless coming with specific complaints related to these systems, is much less likely to receive thorough breast and pelvic examinations (which might detect the prime killers of middle-aged women).

There do not seem to have been any studies of the actual prevalence of fears of one's own body among nonclinical populations of women and men. Such studies would be difficult, if one postulates that displacement of such fears onto symptoms such as backache occurs to an unknown degree. However, there have been a moderate number of studies in recent years on the psychological effects of breast and genital surgery on women (e.g., 96). Most of them have dealt with the effects of surgery for malignancies and thus do not add to our knowledge of the effects of loss of specifically female body parts per se, apart from the frequently associated fear of death from malignancy.

Coitus

The psychology of coital behavior has recently received more clinical and research attention than many other aspects of female psychology. Much of the current thinking and research in this area appears to be a rediscovery of knowledge that was temporarily lost. Late Victorian medical and popular writers have been quoted as believing that "normal" women do not enjoy sexual intercourse, but early Victorian and earlier writers did not share this belief (97). Clitoral anatomy and orgasm were accurately described by early Victorian medical writers (98), who also advocated early marriage, since they believed that women's sexual needs were very strong and if denied might lead to hysteria or other untoward consequences.

Late Victorian and even recent medical writers have tended to define healthy female sexuality primarily in terms of its adaptiveness to male sexual needs (8, 97, 99). Indeed, a fairly recent review of the discussion of female sexuality in gynecology textbooks (8, pp. 283–288) uncovered such remarkable statements as "if a woman after a year of marriage is not able to adapt her sexual needs to those of her husband, medical attention is indicated." The clitoral-vaginal orgasm pseudocontroversy appears to be an example of the same thing. Masters and Johnson (100) have described the physiology of female orgasm, as did Kinsey and associates (101) and early Victorian writers (98).

Clitoral or vaginal stimulation (and occasionally fantasy or breast stimulation) can all evoke orgasm; there are differences in stimulation but not in the physiology of the orgasm itself. Women may subjectively experience clear differences between "little" orgasms (more accurately, relaxation from peak excitement without orgasm proper, which is perhaps analogous to satisfactory intercourse without ejaculation, as is common in older men) and "big" orgasms (or orgasm proper, ac-

companied by spasm of the pubococcygeal muscles). This spasm is perceived vaginally if it is differentiated from the total experience, regardless of whether the evoking stimulation was clitoral or vaginal (102). The spasm may be more intense with clitoral stimulation (100), but it may be more consciously perceived if vaginal stimulation focuses attention on that area. The psychological difference between clitoral and vaginal stimulation clearly has much to do with the fact that an adequate male partner is more often associated with the latter. Whatever the locus of the tactile stimulation, the interpersonal and fantasy aspects of the situation heavily color the woman's subjective experience.

Freud (1) believed that lesser "maturity" was likely to be associated with a preference for clitoral stimulation. In those cases where this is true, such preference might rest on the fact that a woman may need greater maturity and skill in order to effectively communicate her sexual needs to a male partner than to fill them herself. Indeed, contemporary sex therapy approaches as reviewed, for example, by Kaplan (103), tend to emphasize helping both partners to communicate their sensual and sexual feelings and encouraging conditions that are favorable for evoking female orgasm in coitus (such as adequate foreplay, freedom to use the female superior position, an unhurried atmosphere, deconditioning of premature ejaculation, and verbal and nonverbal communication).

There are some interesting differences in the kinds of sex therapy that have been advocated for the two sexes. While most sex therapists today feel strongly that the best results are obtained from working conjointly with a committed couple, it seemed natural to Masters and Johnson to provide surrogate partners for men who lacked a partner willing to participate (104). Medicolegal problems, rather than purely therapeutic ones, forced the abandonment of this program. On the other hand, approaches directed at treating the preorgasmic woman without a participant partner have tended to emphasize a method of teaching her to masturbate to orgasm by means of deconditioning, "permission-giving," sensory awareness, and encouragement (102, 105). The rationale here is to increase her sexual activity and autonomy; she can hardly be expected to communicate her sexual needs and wishes to a partner if she does not know them from her own experience, and she cannot easily be sexually effective if she believes female sexuality to be a passive experience. The fact that most studies have shown that far fewer women than men spontaneously masturbate during adolescence (e.g., reference 101) appears to be consistent with the need for this approach. It is interesting to note that women who go on to high intellectual achievement are more likely to have had active masturbatory lives in adolescence (106).

Sexual dysfunction is said to be extremely common among American couples; Masters and Johnson (104) estimated that up to 50% of all couples are sexually dysfunctional. While no recent and representative large-scale surveys seem to bear directly on this point, it appears that sexual difficulties are common among college populations and that students seeking help at college mental health services do not necessarily voice their difficulties in this area unless they are specifically asked about it (107).

Rape

Forced coitus, that is, rape, is a distinctively human capacity. The recent increase in awareness of psychological consequences of rape or fear of rape has led to a rapidly developing area of psychiatric, sociological, and legal research, recently reviewed by Hilberman (108). Much of the work is clinical and is directed at recommending or evaluating treatment approaches to rape victims or studying psychological characteristics of convicted rapists or known victims. The low rates of reporting rape and seeking treatment, and the even lower rates of conviction, have seriously hampered research in this area. Self-report studies suffer from one kind of sampling bias, but emergency room or prison studies suffer from another. It has therefore been impossible thus far to obtain representative samples of rapists or victims, but a few tentative conclusions can be drawn from available research.

Enduring psychological distress attributed to being raped is not uncommon (109, 110). The insensitive behavior of police and hospital personnel has often been contributory, to the extent that women feel raped a second time. Women have often been victimized rather than protected by attempts at conviction (e.g., court proceedings damaging her reputation, while the defendant's is not admissible as evidence) or prevention (e.g., suggestions that women should stay in at night, thus limiting their vocational and social options). Yet male concern over the possibility of false accusation runs high. In one sample (111), psychiatric treatment for victims had been more often provided and more often perceived as helpful when the victim was a child rather than an adult at the time of the attack. This may have been due in part to the fact that attempts at treatment of adult victims have often focused, like so much in psychotherapy, on the hope of finding a remediable way in which the victim contributed to her own victimization—inadvertently adding to her victimization by blaming her.

The possibility of being raped also affects the psychology of women who have *not* been raped to an as yet unidentified extent. Beginning with early childhood, families provide more chaperonage for daughters than sons (112). Women in cities are more fearful of going out at night than men are. The presumed effects of *fear* of rape are to heighten dependency on men as protectors, yet reported effects of an actual rape are both an increased fear of another rape and, frequently, a wish to avoid men altogether. We do not know at present the extent to which long-lasting post-rape trauma is intrinsic versus iatrogenic, that is, a result of traumatic or inadequate treatment of the victim. Fortunately, there appears to be considerable interest in improving treatment approaches, and a monograph

on rape victims and their treatment has recently been published by the American Psychiatric Association (108).

Childbirth

Childbirth among humans appears to be more variable, more subject to learning, and less "instinctive" than in other animals. Even something as basic as labor pain is enormously variable in amount and characteristics, subject not only to strictly physical variables such as size and position of the infant and the like, but also to prior learning, personal and cultural expectations, obstetrical procedures, and other variables not yet clearly delineated. Until recently, obstetrical catastrophes including postpartum infection were relatively common, and fear of birth was held to be a realistic part of human experience. Thus the parents and social milieu of many of today's mothers may have transmitted a psychology of fear, pain, fatalism, and the like. General taboos on sex education have extended to the subject of childbirth, so that young women are likely to form attitudes about birth many years before accurate information about it is available to them.

Unquestionably, modern medicine and obstetrics have made major and life-saving advances. Maternal and neonatal mortality rates have decreased considerably. This is widely attributed to the "medicalization" of childbirth and use of the hospital for deliveries, although American statistics continue to be less favorable than those of other countries, such as Holland, which use hospital obstetrics more selectively for high-risk births (113). Even in this country the hospital birth is relatively new. A majority of all births occurred at home as recently as 1938, less than two generations ago (114).

At present, a high proportion of maternal deaths and infant complications in America results from anesthesia (115). The need for relief of pain during normal delivery is so intimately bound up with the mother's expectations and training, and the effects of maternal and infant sedation so closely related to formation of the mother-child bond, that management of obstetrical pain and anxiety must be considered a pediatric and psychiatric research area as well as an obstetrical one. Fairly recently, observers within obstetrics, pediatrics, and some consumer groups have scrutinized psychosocial aspects of current obstetrical practices (113, 114, 116, 117), and national and international societies for psychosomatic obstetrics and gynecology have been formed.

Adverse effects of medical procedures. Research (117) has demonstrated the adverse effects of medication on length of labor and infants' arousal level and sucking behavior (sometimes persisting as long as four to seven days). Aspects of hospital milieu and practice, such as unfamiliar environment, presence of strangers, and being moved from one room to another late in labor, have been shown to adversely affect labor in human and infrahuman species (118). The common practice of separating the mother and infant immediately after birth, and maintaining a separation of at least several days punctuated by brief feeding periods, appears to adversely affect the formation of a mother-child bond (119). It is possible that the total exclusion of husband and siblings from contact with the child during the days immediately after birth, coupled with separation from the mother, may adversely affect these other family bonds as well.

The issues here are rather like those involved in the classic studies of hospitalism in infants and children (e.g., reference 120). Procedures undertaken for sound medical rationale, such as provision of treatment and prevention of spread of infection, were shown to be sufficiently disruptive to normal psychological processes that their overall value had to be questioned. The point here is not that these procedures (or some of them) are not often important for the treatment of complications, but that until fairly recently there has been a surprising neglect of the possible profound psychological implications of these procedures and the implication that they are *always* necessary, rather than a standardization of what is *sometimes* necessary.

Indeed, most of the psychiatric studies of adverse psychological responses to the childbirth situation have concentrated on preexisting pathology in the mother (which may, of course, exist) to the exclusion of the effects of the birth situation or the anticipated child-rearing situation (81). I have been unable to locate any outcome study examining the effects of preexisting maternal psychopathology *in interaction with* adverse effects of the birth situation, although it seems highly likely that a woman who is psychologically healthy, and anticipating a wanted child, might be better able to tolerate the customary degrees of psychological interference during the birth process than a less favorably situated woman.

Procedural modifications. Social and consumer movements developing around childbirth and lactation, such as the LaMaze and LaLeche groups (121), have attempted to counter some of these trends, but at times they have also tended to further compromise the mother's sense of mastery (122). For example, contemporary attempts to save what is best in both modern obstetrical practices and in more "natural" methods have primarily addressed themselves to the married couple (e.g., reference 123). Yet one-third of the first-born children in America are conceived outside of marriage (124). While about half of these conceptions are legitimated by marriage, many of the marriages are unstable. Thus the current emphasis on participation by the husband may not offer psychological help to the woman who probably needs it most. It would appear, for example, that an unmarried adolescent mother whose family is ambivalent about or opposed to the birth would have an especially great need for any modification of obstetrical procedures that could enhance her own sense of mastery and adulthood and enhance the mother-child bonding process.

Lactation

Mead and Newton (125) have called lactation a transitional period in the mother-child relationship, the time between birth and weaning from the breast. They noted that in primitive cultures this period may last for years but that in modern America it may be nonexistent. Goodall (126) has noted that in chimpanzees it may last four or five years, thus for this species almost until puberty. Prolonged lactation may be seen as incompatible with the demands of industrial society or simply as too sensual for public indulgence, and it may also be seen as a threat to the marital bond or as an obstruction to shared parenting. The usual American practice is to omit it altogether (most common) or attenuate it with early introduction of solid foods and supplementary bottles.

There are several immediate postpartum physiological advantages of breast feeding. The mother gains the benefits of nipple stimulation with consequent prolactin release and a more rapid uterine involution, and the infant obtains colostrum, which contains valuable antibodies (127). The psychological aspect of breast feeding tends to be either romanticized or neglected; to me it significantly includes fostering a mutual rather than an altruistic beginning of the mother-child relationship. A nursing mother is likely to experience milk let-down at the time the baby cries from hunger; the nursing experience both relieves and indulges the mother and child. Thus from the beginning each is providing comfort to the other. In contrast, bottle feeding is primarily for the baby's sake and provides much less libidinal satisfaction to the mother. It is clearly possible to raise children this way, particularly when they are very much wanted, but current statistics on child abuse suggest that in many cases reliance on altruism for the establishment of the mother-child bond is hazardous (128).

Fertility Control

It is generally believed that safe, reliable, available contraception and abortion are new and are effecting profound changes in the psychology of reproductive life for women. This is both true and not true. Methods of contraception and abortion have been available since antiquity, partially suppressed at times because of religious or moral beliefs, population needs, or concerns about safety or efficacy. In the United States abortion on request and the dissemination of contraceptive and abortifacient knowledge and devices were legal until 1872, when the Comstock laws were passed. Legislative and judicial repeals of barriers to these services have been recent and have been accompanied by advances in both contraceptive knowledge and its dissemination.

Thus, for many women today, the norm of controlling one's own fertility is experienced as relatively new. It follows that there is a cultural lag in assimilating these expectations. Pregnancy is now generally felt to be a matter of choice (whether conscious or unconscious) rather than fate, despite the fact that no temporary method is 100% effective. Thus the expectation of control of conception outstrips the reality. The corollary of increased choice appears to be an enhanced sense of responsibility for the outcome of childbearing, with vulnerability to guilt and other feelings that may interfere with optimal parent-child relationships. In addition, many of the new contraceptive methods carry medical hazards, enhance susceptibility to venereal disease, and can be seen as diminishing the shared responsibility of men.

Accurate information about the medical hazards of birth control pills has not been generally available to most women, although the fact that there are dangers has been disseminated by the public media and is therefore a source of anxiety for many women. Tietze's data (129) suggest that the risk of death from birth control pills is greater than that from childbirth—or from alternative contraceptive approaches including abortion—for all portions of a woman's reproductive career, except for women having frequent intercourse during years of peak fertility. After age 40, in adolescence, or for women having infrequent intercourse, regular use of the pill is not as safe as the alternatives. The safest methods for women—in terms of few side effects and some degree of protection from venereal disease and probably cervical cancer—are the diaphragm and condom, with back-up abortion. These methods have been viewed as psychologically less acceptable to women and/or their partners. The use of condoms, especially if the woman were the one insisting on it, would require a degree of sexual and general assertiveness that has not generally been a part of the behavioral repertoire of women—particularly adolescents, for whom this method would appear to be particularly indicated.

In 1969 Pohlman (130) reviewed research on the psychological aspects of family planning. Like so much of the literature on childbirth and contraception, this work suffers from an emphasis on the married couple; only 5 out of 444 pages of text discuss contraception out of wedlock! With the early adolescent population now the only group in our country showing an increasing birth rate (131), and with the current increase in both divorce rates and the acceptability of childrearing outside of marriage, there is an urgent need for more research bearing on the psychology of family planning outside of the nuclear family.

There has been a series of studies on the psychological effects of abortion (e.g., reference 132). The trend appears clear. Some women do show adverse psychological sequelae but the incidence is lower than for term births. Psychologically (as well as medically), the data support the somewhat startling conclusion that abortion is safer than normal birth. This may be true in part because both internal and external difficulties in arranging abortions still are sufficiently great to make it more likely that the woman who is ambivalent about a pregnancy will carry it to term.

COMMENT

This discussion of women's sexual lives has been presented from a generally heterosexual standpoint. However, most of the same issues apply to lesbian women as well, who may also have functional or dysfunctional sexual relationships, be raped or fear rape, bear children voluntarily or involuntarily, and in general experience most of the same vicissitudes of sexual and reproductive life as do heterosexual women. Some research bearing on issues specific to lesbian lifestyles will be briefly reviewed in part two of this overview, but the topic is sufficiently broad to merit a separate paper.

CONCLUSIONS

We find the sexual and reproductive lives of women to be a rapidly expanding research area of great pertinence to psychiatric theory and practice, with many research questions remaining to be answered. It is clear that much that has been previously assumed to be intrinsic to the psychology of women—or to the vicissitudes of accepting or objecting to the usual consequences of being a woman—needs to be reexamined. While we have not yet entirely ended the specter of involuntary sexuality and involuntary motherhood, or involuntary economic dependence on men, our society appears to be (ambivalently) moving in these directions. When young girls are generally socialized to expect to implement their conscious choices in these matters, women's attitudes toward women's (and men's) sexuality, assertiveness, and nurturance may well turn out to be very different from what is observed today. What we can expect to find will surely include the following:

1. Research done on women by women will often ask different questions and yield different data than research conducted from male points of view on women construed as "the other."
2. Women will continue to have considerable individual differences from each other, as well as similarities.
3. Conscious choices about how to live as a woman will continue to be modified by economic conditions, culture lag in assimilating changes in the realities of women's lives and, undoubtedly, by a host of unconscious factors as well. Intergenerational envy and related conflicts, as well as the conscious and unconscious fears and hopes of men toward women and women's sexuality, will continue to color women's sexual lives.

Researchers will continue to have the task of teasing out these multiple variables in order to understand women's sexuality in the context of other aspects of women's lives as well.

Part two of this overview will attempt to review some of the other aspects of women's lives, although once again we will find as many questions raised as answered—a characteristic of any vitally expanding research area.

Rational Treatment for an Irrational Disorder: What Does the Schizophrenic Patient Need?

BY PHILIP R.A. MAY, M.D.

The author discusses the results of a review of controlled studies of treatment approaches to schizophrenia. Although the research evidence strongly supports the efficacy of pharmacotherapy, this finding should not be interpreted as meaning that all schizophrenic patients should receive antipsychotic drugs or that other forms of treatment are unnecessary. The author cautions against doctrinaire attitudes and advocates thoughtful adjustment of goals and methods to meet the needs of the various parties and situations involved in the treatment of the schizophrenic patient.

TIMES HAVE CHANGED in the treatment of schizophrenia. There are still a few who believe that drugs have no place in the treatment of schizophrenia and that they are incompatible with psychotherapy and psychosocial methods of treatment. This resistance is, however, steadily passing into history.

We have slowly and painfully come to recognize that, despite a plethora of metapsychological, metasocial, and metapharmacological speculation and pontification, we do not yet know the "cause" of schizophrenia; we are forced to admit that all current methods of treatment have serious limitations and may produce unwanted side effects. Schizophrenia is still difficult to treat. There is no miracle cure. Nor is the patient's plight improved when treatment is determined by rote or by doctrinaire prejudices rather than by thoughtful understanding of his needs and their social context and of the nature and limitations of the relevant scientific evidence.

Perhaps we should not be surprised to find that there is resistance to applying the results of scientific research. Max Planck (1), referring to the bitter struggles over his new models of the structure of matter, observed sardonically that "A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die, and a new generation grows up that is familiar with it."

Situations will, of course, arise in which there is little or no scientific evidence and the clinician must necessarily act on the basis of faith, hope, or intuitive judgment. It is essential, however, that he—and his patients, to the extent that they are able—understand the nature of the evidence and the basis for the decisions that are made.

REVIEW OF CONTROLLED STUDIES

Since psychological and social forms of treatment and rehabilitation are expensive and our resources are limited, it is important to know whether drugs potentiate or interfere with the effects of these methods. Is one kind of treatment more useful in some particular stage of the illness, or for some particular purpose?

Now, some 20 years after the introduction of chlorpromazine, we have a new generation of practitioners who are more experienced in pharmacotherapy and more accustomed to scientific controlled studies. It is almost universally held that drugs, psychotherapy, and psychosocial methods should play supplemental rather than competing roles. The general opinion is that drugs have their greatest use in restoring contact and establishing therapeutic relationships during the stage of flagrant psychosis and in maintaining perceptual control later on, during the stage of chronic and subacute illness. Once perceptual control has been reestablished and secondary symptoms have been reduced, and once the patient is in better contact and a relationship has been formed, then psychological and social methods can better work toward mastery of personality difficulties, life problems, and behavioral incapacity.

Despite this apparent general détente, the subject of the interaction of drugs with other therapies has been sadly troubled by dogmatic expressions of opinion and a dearth of well-controlled experimental evidence. I personally prefer systematic observation. I like to know when I am operating on faith and hope rather than on the basis of scientific evidence. This paper therefore will focus on the evidence from controlled studies.

Rating of Studies

A poorly controlled study can be just as misleading

Revised version of a paper presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

Dr. May is Professor of Psychiatry, University of California at Los Angeles, 760 Westwood Plaza, Los Angeles, Calif. 90024, and Chief of Staff, Program Evaluation, Research, and Education, Veterans Administration Hospital (Brentwood), Los Angeles, Calif.

as a report of a single case. Therefore we rated (2–4) on a design-relevance (D-R) scale all studies published before mid-1973 of the results of nonpharmacological therapies in which there were six or more schizophrenic patients treated in the same facility as a control group. Ratings were also assigned to the comparable studies of pharmacological treatment completed before 1968 that were surveyed by Cole and Davis (5). The findings from this group are so definite that inclusion of drug therapy studies completed after 1968 is unnecessary.

Ratings took into account the degree of confidence with which the findings can be applied to the treatment of schizophrenia, the quality of the experimental design, and the analysis of results. On the D-R scale, studies in category I (well executed, well designed, and well analyzed) are given between 84 and 96 points, depending on the number of patients studied and the breadth of the assessment of patient change. Studies in category IV, the lowest included in this review, are given 24 to 36 points.[1]

This procedure makes it possible to assess the weight of the evidence for or against a particular treatment by subtracting the sum of the D-R ratings of studies that found no benefit (or worse) from the sum for studies that reported positive results. The net D-R score gives an estimate of the strength of the supporting evidence.

Milieu Care and Rehabilitation

There was reasonably good evidence (259 D-R points) that inpatient milieu treatment programs produced beneficial results. The programs that were effective had concentrated on real life problems and on planning for discharge. There was little evidence that other types of in-hospital milieu programs were effective in the treatment of schizophrenic patients.

There was also reasonable evidence (150 D-R points) that day care or home care, when practical, was as good as or even better than inpatient treatment, provided that drug treatment was adequately given. There was adequate evidence (369 D-R points) that aftercare programs helped patients remain in the community after discharge from the hospital. The successful programs had focused mainly on problem solving, social adjustment, living arrangements, obtaining employment, and facilitating cooperation with maintenance drug therapy.

Psychotherapy

A breakdown into inpatient versus outpatient and according to type of therapy is illuminating. The balance of the evidence suggested that inpatients treated with individual psychotherapy aimed at psychological understanding did not improve more than a control group (−192 and −51 D-R points, respectively). By contrast, group therapy that was focused on reality or on a group activity was more effective than a control treatment (100 D-R points) and more effective than group therapy aimed at psychological understanding (51 D-R points).

Studies of outpatient psychotherapy were few and far between, but they supported the view that psychotherapy (especially group therapy) is helpful with outpatients: individual casework and rehabilitation was more effective than control (90 D-R points); group therapy was more effective than control (31 D-R points); and group therapy was more effective than individual therapy (64 D-R points). Positive results were obtained particularly when treatment had focused on social and occupational rehabilitation, on problem solving, and on cooperation with pharmacotherapy—i.e., successful treatment was oriented more toward support and rehabilitation than toward formal attempts to promote insight and deeper psychological understanding.

This interpretation of the findings of controlled studies up to mid-1973 is supported by a recent controlled study by Claghorn and associates (6) of outpatient psychotherapy combined with drug therapy. When combined with maintenance drug treatment, group therapy that emphasized the problems and tasks of daily living resulted in a shift toward healthier perceptions of self and others.

Other Forms of Treatment

The greatest evidence of therapeutic effect was gained by antipsychotic drug therapy, which scored many thousands of D-R points. The evidence was negative for nicotinic acid treatment and ECT (−302 and −205 D-R points, respectively). Behavioral conditioning was virtually untested by controlled studies at the time of this review.

Comment

The evidence in favor of the efficacy of pharmacotherapy was overwhelming. This should not prevent us from recognizing that drugs alone are unlikely to be sufficient for an optimal treatment result. Psychosocial interventions may be of crucial importance, particularly in chronic cases and when there is residual disability. Granted, there was only modest evidence (116 D-R points) that inpatient milieu and group psychotherapy programs were of benefit, and then largely if they centered around some kind of activity or focused on discharge planning and social and occupational rehabilitation. There was, however, four times as much evidence (490 D-R points) in favor of outpatient care along similar lines. In fact, day care or home care, when feasible, produced better results than inpatient care (150 D-R points).

Thus there is considerable evidence to underline the value of combining pharmacotherapy and outpatient efforts to reduce residual disability after remission of the acute psychosis and to develop social and occupational skills. The evidence appears small beside the massive weight of the evidence from controlled research on drug therapy, but it is consistent and positive. Per-

[1]Complete information on the studies reviewed, on the D-R scale, and on the various tabulations involved can be found in (2–4).

haps if there were more well-designed studies, this disproportion in weight vis-à-vis drug therapy might be reduced.

DISCUSSION

Do Antipsychotic Drugs Interfere With Psychotherapy and Sociotherapy?

The controlled studies of treatment outcome reviewed by Uhlenhuth and associates (7) and myself (8, 9) indicate that, by the criterion of the ultimate outcome of cases followed from admission, the combination of drugs and psychosocial therapy is quite clearly superior to psychotherapy and sociotherapy alone.

There is, however, no doubt that drugs do not help everybody and that, especially in large doses, they produce troublesome side effects that work against psychological and social therapy. Hence the current controversy on drugs and their toxic effects versus psychotherapy seems to me entirely unnecessary. The proponents of drug therapy focus on main effects and on generalized data for outcome from admission for all patients. The hard-core opposition focuses on toxic effects, on drug failures, and on patients who are given maintenance treatment unnecessarily. Each group touches only a part of the elephant.

The fundamental point is that there is a trade-off between the beneficial antipsychotic effects of a drug and its adverse side effects. The optimum trade-off point varies from patient to patient and according to the immediate goals of treatment at any particular time. When patients are "snowed" with drugs, they obviously cannot benefit from social or psychological treatment (10). There is also no doubt that some patients are continued on drug treatment too long, or at higher (or lower) than optimal dosages (11). The skill in drug therapy is to avoid large doses except in the early stages of treatment or in unusual situations and to monitor the treatment process closely so that dosage can be adjusted to the trade-off point that is optimal for the current goals of treatment. In general, the closer the patient becomes to "normal," the more we should be careful to reduce drug dosage to the minimum required for maintenance of perceptual control.

I have never been entirely able to understand why Freud's views on psychopharmacology have been so generally ignored. Indeed, as Byck (12) points out in another context, Freud should be considered one of the founders and pioneers of psychopharmacology. He introduced a systematic scientific methodology to the study of centrally active drugs and considered in his papers a number of issues that have become major issues in modern psychopharmacology. He also consistently maintained that pharmacotherapy would eventually become a central aspect of treatment not in opposition to psychoanalysis or other forms of treatment.

In 1914 Freud wrote: ". . . all . . . provisional ideas in psychology will presumably some day be based on an organic substructure. This makes it probable that it is special substances and chemical processes which perform the operations of . . . special psychical forces" (13, p. 78). In 1930 he said "The hope of the future . . . lies in organic chemistry or access to it through endocrinology. This future is still far distant, but one should study analytically every case of psychosis because this knowledge will one day guide the chemical therapy" (14, p. 449).

Freud later (1933) took the position that psychoanalysis did not stand in opposition to other treatment methods, diminish their value, or exclude them. He also expressed the hope that hormones might eventually provide us with a means of coping successfully with the (hypothesized) maldistribution of energy in the psychoses (15). In 1938 Freud concluded that "The future may teach us to exercise a direct influence, by means of particular chemical substances, on the amounts of energy and their distribution in the neural apparatus. It may be that there are other still undreamt-of possibilities of therapy. But for the moment we have nothing better at our disposal than the technique of psychoanalysis" (16, p. 182).

The Nature of Drug Effect

It is commonly asserted that drug therapy acts only to reduce anxiety and is "superficial" or "only supportive." This is not in line with the evidence from controlled studies showing that drugs affect the primary symptoms of schizophrenia more than the secondary ones (2). The implication is that antipsychotic drugs reduce psychotic distortion of reality and thus reduce the anxiety secondary to that distortion.

It is reasonable to assume that lifetime patterns are not likely to be easily modified, and to be suspicious of any suggestion that short-term treatment of any kind can promote radical change. But there is virtually no information available about change at "deeper" levels over a prolonged period resulting from *any* type of therapy, and certainly no experimental support for the notion that more such change occurs during psychosocial treatments than during an equivalent period of drug therapy.

On the other side of the fence, there is no hard evidence that psychological and social treatments are any more than palliative; they help some persons to make the best use of their resources, rather than actually remedying the primary disorder, whatever that may be.

Therapeutic Relationships and Psychopharmacotherapy

It is frequently assumed that drug treatment requires no particular skill and no particular attention to the transactions of the therapeutic relationship. This is a serious error. The effectiveness of any kind of treatment depends on a good relationship with the patient and his family, and the vicissitudes of these relationships have a profound impact on the course of pharma-

cotherapy. Establishing a continuing positive relationship must therefore occupy a central position in the overall strategy for treating the schizophrenic patient, whatever the form of treatment employed.
